5. Verify the ptp servo on SW2.

```
BC# sh ptp servo
PTP servo status for clock 0
  Servo Config                : Phase Correction
  Servo State                 : Normal Loop
  Servo State Duration        : 00:20:46
  Servo APTS Mode             : N/A
  Frequency Correction        : 0.000 ppb
  Phase Correction            : -3537.000 nsec
  Offset From Master          : -479.000 nsec
  Mean Path Delay             : 3536 nsec
  APTS GPS to PTP Offset      : 0 nsec
  Sync Packet Rate            : 16
  Delay Packet Rate           : 16
```

Note: Use show ptp stats to collect the PTP statistics and use clear ptp stats to clear the same.

CHAPTER 3 PTP G.8275.2 Profile Configuration

This chapter shows how to configure a PTP G.8275.2 profile over IPv4 and IPv6. You configure T-GM and boundary clock with more than one port.

Note: We can enable G.8275.2 on L3 interfaces, sub interfaces and member port of the LAG.

Partial Timing Support (PTS) Topology

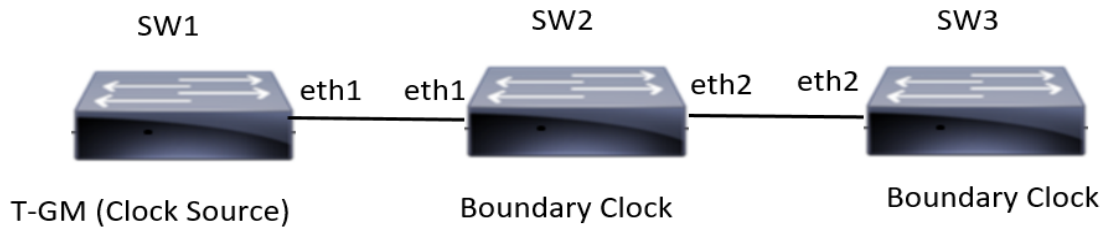

Figure 3-115: Configuration Topology

In this example, SW1, SW2 and SW3 are running PTP. SW1 acting as T-GM and SW2, SW3 acting as boundary clock.

PTS G.8275.2 Profile Configuration

This section shows how to set up a G.8275.2 Profile.

SW2 (boundary clock)

`#configure terminal`	Enter Configure mode
`(config)#synce`	Enter configure Synchronous Ethernet mode.
`(config-synce)#synchronization option 1`	Set the synchronization network type.
`(config-synce)#exit`	Exit Synce mode
`(config)#synce-interface ptp`	Configure synce interface ptp
`(config-synce-if)# mode synchronous`	Configure synchronous mode
`(config-synce-if)# quality-level QL_PRC`	Configure QL-value.
`(config-synce-if)# input-source 1`	Configure the interface as an input source with priority 1
`(config-synce-if)# wait-to-restore 0`	Configure Wait-to-Restore timer.
`(config-synce-if)# exit`	Exit Port Configure mode.
`(config)# interface eth1`	Configure interface eth1
`(config-if)# ip address 192.168.4.101/24`	Configure the IP address of the interface.
`(config-synce-if)# exit`	Exit synce Configure mode.
`(config)#interface eth2`	Configure interface eth2
`(config-if)# ip address 192.168.5.100/24`	Configure the IP address of the interface.
`(config-if)#exit`	Exit interface mode
`(config)#ptp clock profile g8275.2`	Enables G8275.2 for PTP time/phase telecom profile
`(config-ptp-clk)#number-ports 2`	Configure the number of PTP ports on the instance
`(config-ptp-clk)#clock-port 1`	Configure ptp port
`(config-clk-port)# transport ipv4`	Set transport type ipv4
`(config-clk-port)#network-interface eth1`	Configure underlying interface that is used by this PTP Port
`(config-clk-port)#master ipv4 192.168.4.100`	Set master clock source address
`(config-clk-port)# exit`	Exit ptp clock port mode
`(config-ptp-clk)#clock-port 2`	Configure ptp port
`(config-clk-port)#transport ipv4`	Set transport type ipv4
`(config-clk-port)#network-interface eth2`	Configure underlying interface that is used by this PTP Port
`(config-clk-port)#exit`	Exit ptp clock port mode

SW3 (Boundary clock)

`#configure terminal`	Enter Configure mode
`(config)#synce`	Enter configure Synchronous Ethernet mode.
`(config-synce)#synchronization option 1`	Set the synchronization network type.
`(config-synce)#exit`	Exit Synce mode
`(config)#synce-interface ptp`	Configure synce interface ptp
`(config-synce-if)# mode synchronous`	Configure synchronous mode
`(config-synce-if)# quality-level QL_PRC`	Configure QL-value.
`(config-synce-if)# input-source 1`	Configure the interface as an input source with priority 1
`(config-synce-if)# wait-to-restore 0`	Configure Wait-to-Restore timer.
`(config-synce-if)# exit`	Exit Port Configure mode.
`(config)# interface eth1`	Configure interface eth1
`(config-if)# ip address 192.168.4.101/24`	Configure the IP address of the interface.
`(config-synce-if)# exit`	Exit synce Configure mode.
`(config)#interface eth2`	Configure interface eth2
`(config-if)# ip address 192.168.5.100/24`	Configure the IP address of the interface.
`(config-if)#exit`	Exit interface mode
`(config)#ptp clock profile g8275.2`	Enables G8275.2 for PTP time/phase telecom profile
`(config-ptp-clk)#number-ports 2`	Configure the number of PTP ports on the instance
`(config-ptp-clk)#clock-port 1`	Configure ptp port
`(config-clk-port)# transport ipv4`	Set transport type ipv4
`(config-clk-port)#network-interface eth1`	Configure underlying interface that is used by this PTP Port
`(config-clk-port)#master ipv4 192.168.4.100`	Set master clock source address
`(config-clk-port)# exit`	Exit ptp clock port mode
`(config-ptp-clk)#clock-port 2`	Configure ptp port
`(config-clk-port)#transport ipv4`	Set transport type ipv4
`(config-clk-port)#network-interface eth2`	Configure underlying interface that is used by this PTP Port
`(config-clk-port)#exit`	Exit ptp clock port mode

SW1 (T-GM)

`#configure terminal`	Enter Configure mode
`(config)#synce`	Enter configure Synchronous Ethernet mode.
`(config-synce)#synchronization option 1`	Set the synchronization network type.
`(config-synce)#exit`	Exit Synce mode
`(config)#synce-interface gps`	Configure synce interface gps
`(config-synce-if)# mode synchronous`	Configure synchronous mode
`(config-synce-if)# input-source 1`	Configure the interface as an input source with priority 1
`(config-synce-if)# quality-level QL_PRC`	Configure QL-value.
`(config-synce-if)# wait-to-restore 1`	Configure Wait-to-Restore timer.
`(config-synce-if)#exit`	Exit Port Configure mode
`(config)#synce-interface ptp`	Configure synce interface ptp
`(config-synce-if)# mode synchronous`	Configure synchronous mode
`(config-synce-if)# quality-level QL_PRC`	Configure QL-value.
`(config-synce-if)# input-source 2`	Configure the interface as an input source with priority 2
`(config-synce-if)# wait-to-restore 0`	Configure Wait-to-Restore timer.
`(config-synce-if)# exit`	Exit Port Configure mode.
`(config)#interface eth2`	Configure interface eth2
`(config-if)#ip address 192.168.4.100/24`	Configure the IP address of the interface.
`(config-if)#exit`	Exit interface mode
`(config)#ptp clock profile g8275.2`	Enables G8275.2 for PTP time/phase telecom profile
`(config-ptp-clk)#number-ports 2`	Configure the number of PTP ports on the instance
`(config-ptp-clk)#clock-port 2`	Configure ptp port
`(config-clk-port)# transport ipv4`	Configure the port as an master-only port
`(config-clk-port)#network-interface eth2`	Configure underlying interface that is used by this PTP Port
`(config-clk-port)# master-only`	Configure the port as an master-only port
`(config-clk-port)#exit`	Exit ptp clock port mode
`(config-ptp-clk)#clock-port 1`	Configure ptp port
`(config-clk-port)#network-interface gps`	Configure underlying interface that is used by this PTP Port
`(config-clk-port)#exit`	Exit ptp clock port mode

Validation

SW2

1. Verify the default data set on SW2.

```
# BC#show ptp clock dataset default
  Two Step Flag               : No
  Clock Identity              : E8:C5:7A:FF:FE:02:A0:3C
  Number Of Ports             : 2
```

```
  Priority1                   : 128
  Priority2                   : 128
  Slave Only                  : No
  Local Priority              : 128
  Max Steps Removed           : 255
  Domain Number               : 44
  Clock Quality               :
    Clock Class               : 248
    Clock Accuracy            : 254
    Offset ScaledLogVariance  : 65535
```

2. Verify the current data set on SW2.

```
# show ptp clock dataset current
  Steps Removed               : 1
  Offset From Master          : -131072 (-2.000 nsec)
  Mean Path Delay             : 3060
```

3. Verify the parent data set on SW2.

```
# show ptp clock dataset parent
  Parent Port ID              :
    Clock Identity            : 00:00:00:00:00:00:00:01
    Port Number               : 1
  Parent Stats                : No
  Observed Parent O.S.L.V     : 0 (Offset Scaled Log Variance)
  Observed Parent P.C.R.      : 0 (Phase Change Rate)
  Grandmaster Identity        : 00:00:00:00:00:00:00:01
  Grandmaster Priority1       : 128
  Grandmaster Priority2       : 128
  Grandmaster Clock Quality   :
    Clock Class               : 6
    Clock Accuracy            : 33
    Offset ScaledLogVariance  : 20061
```

4. 4. Verify the port state on SW2.

```
# sh ptp port
Port 1:
  Port State                  : Slave
  Port Identity               : E8:C5:7A:FF:FE:02:A0:3C:00:01
  Log Min Delay Req Interval  : -6
  Peer Mean Path Delay        : 0
  Log Announce Interval       : -3
  Announce Receipt Timeout    : 3
  Log Sync Interval           : -6
  Delay Mechanism             : End to end
  Version Number              : 2
  Local Priority              : 128
  Master only                 : False
  Signal Fail                 : False
```

```
  Network Interface           : eth1
  Vlan Configured             :
  Description                 :
  TTL                         : 64

  log Announce Interval       : -3
  log Sync Interval           : -6
  Log Delay Req Interval      : -6
```

5. Verify the ptp servo on SW2.

```
# sh ptp servo
PTP servo status for clock 0
  Servo Config                : Freq + Phase Correction
  Servo State                 : Time Locked
  Servo State Duration        : 00:13:33
  Servo APTS Mode             : PTP
  Frequency Correction        : -0.674 ppb
  Phase Correction            : 0.000 nsec
  Offset From Master          : 10.000 nsec
  Mean Path Delay             : 3060 nsec
  APTS GPS to PTP Offset      : 0 nsec
  Sync Packet Rate            : 64
  Delay Packet Rate           : 65
```

Note: Use show ptp stats to collect the PTP statistics and use clear ptp stats to clear the same.

Asserted Partial Timing Support (APTS) Topology

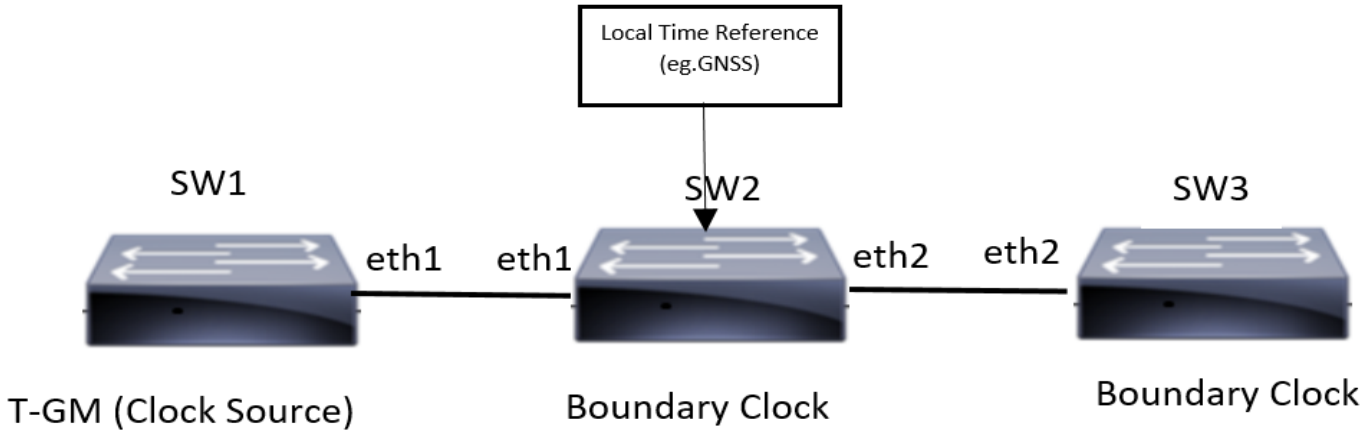

Figure 3-116: Configuration Topology

In this example, SW1, SW2 and SW3 are running PTP. SW1 acting as T-GM and SW2, SW3 acting as boundary clock.

APTS G.8275.2 Profile Configuration

This section shows how to set up a G.8275.2 Profile.

SW2 (boundary clock)

`#configure terminal`	Enter Configure mode
`(config)#synce`	Enter configure Synchronous Ethernet mode.
`(config-synce)#synchronization option 1`	Set the synchronization network type.
`(config-synce)#exit`	Exit Synce mode
`(config)#synce-interface gps`	Configure synce interface gps
`(config-synce-if)# mode synchronous`	Configure synchronous mode
`(config-synce-if)# input-source 1`	Configure the interface as an input source with priority 1
`(config-synce-if)# quality-level QL_PRC`	Configure QL-value.
`(config-synce-if)# wait-to-restore 1`	Configure Wait-to-Restore timer.
`(config-synce-if)# exit`	Exit Port Configure mode.
`(config)#synce-interface ptp`	Configure synce interface ptp
`(config-synce-if)# mode synchronous`	Configure synchronous mode
`(config-synce-if)# quality-level QL_PRC`	Configure QL-value.
`(config-synce-if)# input-source 2`	Configure the interface as an input source with priority 2
`(config-synce-if)# wait-to-restore 0`	Configure Wait-to-Restore timer.
`(config-synce-if)# exit`	Exit Port Configure mode.
`(config)# interface eth1`	Configure interface eth1
`(config-if)# ip address 192.168.4.101/24`	Configure the IP address of the interface.
`(config-synce-if)# exit`	Exit synce Configure mode.
`(config)#interface eth2`	Configure interface eth2
`(config-if)# ip address 192.168.5.100/24`	Configure the IP address of the interface.
`(config-if)#exit`	Exit interface mode
`(config)#ptp clock profile g8275.2`	Enables G8275.2 for PTP time/phase telecom profile
`(config-ptp-clk)#number-ports 3`	Configure the number of PTP ports on the instance
`(config-ptp-clk)#clock-port 1`	Configure ptp port
`(config-clk-port)#network-interface gps`	Configure underlying interface that is used by this PTP Port
`(config-clk-port)#exit`	Exit ptp clock port mode
`(config-ptp-clk)#clock-port 2`	Configure ptp port
`(config-clk-port)# transport ipv4`	Set transport type ipv4
`(config-clk-port)#network-interface eth1`	Configure underlying interface that is used by this PTP Port
`(config-clk-port)#master ipv4 192.168.4.100`	Set master clock source address
`(config-clk-port)# exit`	Exit ptp clock port mode
`(config-ptp-clk)#clock-port 3`	Configure ptp port
`(config-clk-port)#transport ipv4`	Set transport type ipv4
`(config-clk-port)#network-interface eth2`	Configure underlying interface that is used by this PTP Port
`(config-clk-port)#exit`	Exit ptp clock port mode

SW3 (Boundary clock)

`#configure terminal`	Enter Configure mode
`(config)#synce`	Enter configure Synchronous Ethernet mode.
`(config-synce)#synchronization option 1`	Set the synchronization network type.
`(config-synce)#exit`	Exit Synce mode
`(config)#synce-interface ptp`	Configure synce interface gps
`(config-synce-if)# mode synchronous`	Configure synchronous mode
`(config-synce-if)# quality-level QL_PRC`	Configure QL-value.
`(config-synce-if)# input-source 1`	Configure the interface as an input source with priority 1
`(config-synce-if)# wait-to-restore 0`	Configure Wait-to-Restore timer.
`(config-synce-if)# exit`	Exit Port Configure mode.
`(config)#interface eth2`	Configure interface eth2
`(config-if)#ip address 192.168.5.101/24`	Configure eth2 as Layer 2 port
`(config-if)#exit`	Exit interface mode
`(config)#ptp clock profile g8275.2`	Enables G8275.2 for PTP time/phase telecom profile
`(config-ptp-clk)#number-ports 1`	Configure the number of PTP ports on the instance
`(config-ptp-clk)#clock-port 1`	Configure ptp port
`(config-clk-port)#network-interface eth2`	Configure underlying interface that is used by this PTP Port
`(config-clk-port)#transport ipv4`	Set transport type ipv4.
`(config-clk-port)#master ipv4 192.168.5.100`	Set master clock source address.
`(config-clk-port)#exit`	Exit ptp clock port mode

SW1 (T-GM)

`#configure terminal`	Enter Configure mode
`(config)#synce`	Enter configure Synchronous Ethernet mode.
`(config-synce)#synchronization option 1`	Set the synchronization network type.
`(config-synce)#exit`	Exit Synce mode
`(config)#synce-interface gps`	Configure synce interface gps
`(config-synce-if)# mode synchronous`	Configure synchronous mode
`(config-synce-if)# input-source 1`	Configure the interface as an input source with priority 1
`(config-synce-if)# quality-level QL_PRC`	Configure QL-value.
`(config-synce-if)# wait-to-restore 1`	Configure Wait-to-Restore timer.
`(config-synce-if)#exit`	Exit Port Configure mode
`(config)#synce-interface ptp`	Configure synce interface gps
`(config-synce-if)# mode synchronous`	Configure synchronous mode
`(config-synce-if)# quality-level QL_PRC`	Configure QL-value.
`(config-synce-if)# input-source 2`	Configure the interface as an input source with priority 2
`(config-synce-if)# wait-to-restore 0`	Configure Wait-to-Restore timer.
`(config-synce-if)# exit`	Exit Port Configure mode.
`(config)#interface eth2`	Configure interface eth2
`(config-if)#ip address 192.168.4.100/24`	Configure the IP address of the interface.
`(config-if)#exit`	Exit interface mode
`(config)#ptp clock profile g8275.2`	Enables G8275.2 for PTP time/phase telecom profile
`(config-ptp-clk)#number-ports 2`	Configure the number of PTP ports on the instance
`(config-ptp-clk)#clock-port 2`	Configure ptp port
`(config-clk-port)# transport ipv4`	Configure the port as an master-only port
`(config-clk-port)#network-interface eth2`	Configure underlying interface that is used by this PTP Port
`(config-clk-port)# master-only`	Configure the port as an master-only port
`(config-clk-port)#exit`	Exit ptp clock port mode
`(config-ptp-clk)#clock-port 1`	Configure ptp port
`(config-clk-port)#network-interface gps`	Configure underlying interface that is used by this PTP Port
`(config-clk-port)#exit`	Exit ptp clock port mode

Validation

SW2

1. Verify the default data set on SW2.

```
BC# show ptp clock dataset default
  Two Step Flag               : No
  Clock Identity              : E8:C5:7A:FF:FE:23:6E:1C
  Number Of Ports             : 3
  Priority1                   : 128
  Priority2                   : 128
```

```
  Slave Only                  : No
  Local Priority              : 128
  Max Steps Removed           : 255
  Domain Number               : 44
  Clock Quality               :
    Clock Class               : 248
    Clock Accuracy            : 254
    Offset ScaledLogVariance  : 65535
```

2. Verify the current data set on SW2.

```
BC#show ptp clock dataset current
  Steps Removed               : 1
  Offset From Master          : 0 (0.000 nsec)
  Mean Path Delay             : 0
```

3. Verify the parent data set on SW2.

```
BC#show ptp clock dataset parent
  Parent Port ID              :
    Clock Identity            : 00:00:00:00:00:00:00:01
    Port Number               : 1
  Parent Stats                : No
  Observed Parent O.S.L.V     : 0 (Offset Scaled Log Variance)
  Observed Parent P.C.R.      : 0 (Phase Change Rate)
  Grandmaster Identity        : 00:00:00:00:00:00:00:01
  Grandmaster Priority1       : 128
  Grandmaster Priority2       : 128
  Grandmaster Clock Quality   :
    Clock Class               : 6
    Clock Accuracy            : 33
    Offset ScaledLogVariance  : 20061
```

4. Verify the port state on SW2.

```
BC#sh ptp port
Port 1:
  Port State                  : Slave
  Port Identity               : E8:C5:7A:FF:FE:23:6E:1C:00:01
  Peer Mean Path Delay        : 0
  Log Announce Interval       : -3
  Log Min Delay Req Interval  : 127
  Log Sync Interval           : -6
  Announce Receipt Timeout    : 3
  Delay Mechanism             : End to end
  Version Number              : 2
  Local Priority              : 0
  Master only                 : False
  Signal Fail                 : False
  Network Interface           : gps
  Vlan Configured             :
  Description                 :
```

```
  TTL                          : 64
  DSCP                         : 56
  Unicast Grant Duration       : 300
  Configured delay asymmetry   : 0 nsec

  Received Packets             : 0
  Discarded Packets            : 0
  Transmitted Packets          : 0

Port 2:
  Port State                   : Slave
  Port Identity                : E8:C5:7A:FF:FE:23:6E:1C:00:02
  Peer Mean Path Delay         : 0
  Log Announce Interval        : -3
  Log Min Delay Req Interval   : -6
  Log Sync Interval            : -6
  Announce Receipt Timeout     : 3
  Delay Mechanism              : End to end
  Version Number               : 2
  Local Priority               : 128

  Delay Mechanism             : End to end
  log Announce Interval       : -3
  log Sync Interval           : -6
```

```
  Log Delay Req Interval      : -6
```

5. Verify the ptp servo on SW2.

```
BC# sh ptp servo
PTP servo status for clock 0
  Servo Config                : Freq + Phase Correction
  Servo State                 : Time Locked
  Servo State Duration        : 00:11:17
  Servo APTS Mode             : GPS
  Frequency Correction        : 0.002 ppb
  Phase Correction            : 0.000 nsec
  Offset From Master          : 0.000 nsec
  Mean Path Delay             : 0 nsec
  APTS GPS to PTP Offset      : 32723445187 nsec
  Sync Packet Rate            : 0
  Delay Packet Rate           : 0
```

Note: Use show ptp stats to collect the PTP statistics and use clear ptp stats to clear the same.

Precision Time Protocol Command Reference

Contents

This document contains these chapters:

CHAPTER 1 PTP 8275.1 and PTP 8275.2 Commands

This chapter contains the configuration commands used for Precision Time Protocol (PTP). It includes the following commands:

- show ptp servo history
- slave-only
- show ptp stats
- slave-only
- source-address
- Transport
- ttl
- unicast-grant-duration

1pps-out offset

Use this command to set 1PPS external interface output signal offset in nano seconds.

Use no form of this command to set default value 0.

Command Syntax

```
1pps-out offset <-2048-2048>
no 1pps-out offset
```

Parameters

<-2048-2048>	Offset value in range. Default is 0

Command Mode

PTP Clock Mode

Default

Default offset value is Zero.

Applicability

This command was introduced in OcNOS-SP version 4.0.

Example

```
#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
(config)#ptp clock profile g8275.1
OcNOS(config-ptp-clk)#1pps-out offset ?
  <-2048-2048>  Offset value in range. Default is 0
(config-ptp-clk)#1pps-out offset 2048
```

announce-receipt-timeout

Use this command to set announce-receipt-timeout. Applicable for only G.8275.2 profile.

Use no form of this command to set default value 3.

Command Syntax

```
announce-receipt-timeout <2-10>
no announce-receipt-timeout
```

Parameters

<2-10>	announceReceiptTimeout range (default is 3)

Command Mode

PTP Clock Port Mode

Default

Default offset value is Zero.

Applicability

This command was introduced in OcNOS-SP version 4.0.

Example

```
#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
(config)#
(config)#ptp clock profile g8275.1
(config-ptp-clk)#clock-port 1
(config-clk-port)#announce-receipt-timeout 3
```

clear ptp stats

Use this command to clear PTP packet statistics.

Command Syntax

```
clear ptp stats
```

Parameters

None

Command Mode

Privileged Exec mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

.Example

```
#clear ptp stats
```

clock-accuracy

Use this command to indicate the expected accuracy of the clock.

Note: Applicable for Non-Ethernet ports for PTP Clock Port mode.

Command Syntax

```
clock-accuracy <0-255>
no clock-accuracy
```

Parameters

<0-255>	A number representing the expected clock accuracy.

Command Mode

PTP Clock Mode and PTP Clock Port Mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
#configure terminal
(config)#ptp clock profile g8275.1
(config-ptp-clk)#clock-accuracy 10
```

Note: Use no form of this command in PTP Clock Mode to set default value 254.

```
(config-ptp-clk)#clock-port 1
(config-clk-port)#clock-accuracy 15
```

Note: Use no form of this command in PTP Clock Port Mode to set default value 0x21.

clock-class

Use this command to denote the traceability of the time or frequency distributed by the clock.

Note: Applicable for Non-Ethernet ports for PTP Clock Port mode.

Command Syntax

```
clock-class <0-255>
no clock-class
```

Parameters

<0-255>	A number representing the traceability of time or frequency of the clock.

Command Mode

PTP Clock Mode and PTP Clock Port Mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
#configure terminal
(config)#ptp clock profile g8275.1
(config-ptp-clk)#clock-class 3
```

Note: Use no form of this command in PTP Clock Mode to set default value 248.

```
(config-ptp-clk)#clock-port 1
(config-clk-port)#clock-class 7
```

Note: Use no form of this command in PTP Clock Port Mode to set default value 6 for clock-port.

clock-port

Use this command to enter PTP Clock Mode. To remove the clock-port configuration, use the no form of the command.

Command Syntax

```
clock-port <1-31>
no clock-port <1-31>
```

Parameters

<1-32>	Port number

Command Mode

PTP Clock Mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
# configure terminal
(config)#ptp clock profile g8275.1
(config-ptp-clk)#clock-port 1
(config-clk-port)#
```

delay-asymmetry

Use this command to set asymmetric delay in nanoseconds.

Use no form of this command to set default value 0.

Command Syntax

```
delay-asymmetry {msec <-100-100>|nsec <-1000000-1000000>}
no delay-asymmetry
```

Parameters

`msec <-100-100>`	Value of latency in msec.
`nsec<-1000000-1000000>`	Value of latency in nsec.

Command Mode

PTP Clock Port mode

Applicability

This command introduced in OcNOS-SP version 4.0.

Example

```
#configure terminal
Enter configuration commands, one per line.End with CNTL/Z. (config)#
(config)#ptp clock profile g8275.2 (config-ptp-clk)#clock-port 1
(config-clk-port)# delay-asymmetry msec 100 nsec 1000000
```

description

Use this command to set description for clock port.

Use no form of this command to delete this description.

Command Syntax

```
description LINE
no description
```

Parameters

LINE	Characters describing this clock port.

Command Mode

PTP Clock Port Mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
# configure terminal
(config)#ptp clock profile g8275.1
(config-ptp-clk)#clock-port 1
(config-clk-port)#description l3
```

domain

Use this command to set the current synchronization domain. For the G.8275.1 profile, valid domain numbers are in the range of 24 - 43 and default is 24. For the G.8275.2 profile, valid domain numbers are in the range of 44 - 63 and default is 44.

Command Syntax

```
domain <24-63>
no domain
```

Parameters

<24-63>	A numerical value that represents a synchronization domain.

Command Mode

PTP Clock Mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
# configure terminal
(config)#ptp clock profile g8275.1
(config-ptp-clk)#domain 30
```

dscp

Use this command to set dscp value. Applicable for g.8275.2 profile.

Use no form of this command to set default value 56.

Command Syntax

```
dscp <0-63>
no dscp
```

Parameters

`<0-63>` Setting dscp value (default is 56)

Command Mode

PTP Clock Port mode

Applicability

This command introduced in OcNOS-SP version 4.0.

Example

```
#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
(config)#
(config)#ptp clock profile g8275.2
(config-ptp-clk)#clock-port 1
(config-clk-port)#dscp 2
```

gps-offset

Use this command to set GPS offset in nano seconds ans seconds.

Use no form of this command to set default value 0 nsec.

Command Syntax

```
gps-offset (sec <-100-100> | nsec <-2048-2048>)
no gps-offset
```

Parameters

`sec <-100-100>`	Offset value in seconds.
`nsec<-2048-2048>`	Offset value in nano seconds.

Command Mode

PTP Clock Mode

Applicability

This command was introduced in OcNOS-SP version 4.0.

Example

```
#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
(config)#
(config)#ptp clock profile g8275.1
(config-ptp-clk)#gps-offset sec 100 nsec 2048
```

grandmaster-priority2

Use this command to set grandmaster-priority2 for virtual-clock-port. Applicable for g.8275.1 profile. Not applicable to Ethernet interfaces.

Use no form of this command to set priority2 default value 128.

Command Syntax

```
grandmaster-priority2 <0-255>
no grandmaster-priority2
```

Parameters

<0-255>	Priority range

Command Mode

PTP Clock Port Mode

Applicability

This command was introduced in OcNOS-SP version 4.0.

Example

```
#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
(config)#
(config)#ptp clock profile g8275.1
(config-ptp-clk)#clock-port 1
(config-clk-port)#grandmaster-priority2 2
```

holdover

Use this command to enable holdover.

Use no form of this command to set default duration 120.

Command Syntax

```
holdover <0-1440>
no holdover
```

Parameters

<0-1440>	Range of holdover in minutes.

Command Mode

PTP Clock Mode

Default

Default holdover minutes is 120.

Applicability

This command was introduced in OcNOS-SP version 4.0.

Example

```
#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
(config)#
(config)#ptp clock profile g8275.1
(config-ptp-clk)#holdover 15
```

local-priority (ptp-clk mode)

Use this command to specify the local attribute of the local clock.

Use no form of this command to set default value 128.

Command Syntax

```
local-priority <1-255>
no local-priority
```

Parameters

<1-255>	A numerical value specifying the local priority

Command Mode

PTP Clock Mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
# configure terminal
(config)#ptp clock profile g8275.1
(config-ptp-clk)#local-priority 100
```

local-priority (ptp-clk-port mode)

Use this command to specify the local attribute of the local clock.

Use no form of this command to set default value 128.

Command Syntax

```
local-priority <1-255>
no local-priority
```

Parameters

<1-255>	A numerical value specifying the local priority

Command Mode

PTP Clock Port Mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
# configure terminal
(config)#ptp clock profile g8275.1
(config-ptp-clk)#clock-port 5
(config-clk-port)#local-priority 50
```

log-announce-interval

Use this command to set log-announce-interval. Applicable for only G.8275.2 profile.

Use no form of this command to set default value -3.

Command Syntax

```
log-announce-interval <-3-0>
no log-announce-interval
```

Parameters

<-3-0>	logAnnounceInterval range (default is -3)

Command Mode

PTP Clock Port Mode

Applicability

This command was introduced in OcNOS-SP version 4.0.

Example

```
#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
(config)#
(config)#ptp clock profile g8275.1
(config-ptp-clk)#clock-port 1
(config-clk-port)#log-announce-interval -2
```

log-min-delay-req-interval

Use this command to set log-min-delay-req-interval. Applicable for only G.8275.2 profile.

Use `no` form of this command to set default value -6.

Command Syntax

```
log-min-delay-req-interval <-7-0>
no log-min-delay-req-interval
```

Parameters

`<-7-0>`	minDelayReqInterval range (default is -6)

Command Mode

PTP Clock Port mode

Applicability

This command introduced in OcNOS-SP version 4.0.

Example

```
#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
(config)#
(config)#ptp clock profile g8275.1
(config-ptp-clk)#clock-port 1
(config-clk-port)#log-min-delay-req-interval -5
```

log-sync-interval

Use this command to set log-sync-interval. Applicable for only G.8275.2 profile.

Use no form of this command to set default value -6.

Command Syntax

```
log-sync-interval <-7-0>
no log-sync-interval
```

Parameters

<-7-0>	logSyncInterval range (default is -6)

Command Mode

PTP Clock Port mode

Applicability

This command introduced in OcNOS-SP version 4.0.

Example

```
OcNOS#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
(config)#
(config)#ptp clock profile g8275.1
(config-ptp-clk)#clock-port 1
(config-clk-port)#log-sync-interval -4
```

master

Use this command to configure master ipv4 and ipv6 address. Applicable for g.8275.2 profile.

Use no form of this command to delete master address.

Command Syntax

```
master (ipv4 A.B.C.D|ipv6 X:X::X:X)
no master (ipv4 A.B.C.D|ipv6 X:X::X:X)
```

Parameters

ipv4	Setting master ipv4 address
A.B.C.D	Setting ipv4 clock source
ipv6	Setting master ipv6 address
X:X::X:X	Setting ipv6 clock source

Command Mode

PTP Clock Port mode

Applicability

This command introduced in OcNOS-SP version 4.0.

Example

```
#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
(config)#
(config)#ptp clock profile g8275.2
(config-ptp-clk)#clock-port 1
(config-clk-port)#transport ipv4
(config-clk-port)#master ipv4 10.1.1.2
```

master-only

Use this command to set a port to a master-only port.

Use no form of this command to delete this configuration.

Command Syntax

```
master-only
no master-only
```

Parameters

None

Command Mode

PTP Clock Port Mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
# configure terminal
(config)#ptp clock profile g8275.1
(config-ptp-clk)#clock-port 10
(config-clk-port)#master-only
```

max-steps-removed

Use this command to specify the maximum number of communication paths between the local clock and the grandmaster clock.

Use no form of this command to set default value 255.

Command Syntax

```
max-steps-removed <1-255>
no max-steps-removed
```

Parameters

<1-255>	The number of communication links between the local clock and the grandmaster clock.

Command Mode

PTP Clock Mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
# configure terminal
(config)#ptp clock profile g8275.1
(config-ptp-clk)#max-steps-removed 10
```

network-interface

Use this command to reference the configured underlying interface that is used by this PTP Port.

Use no form of this command to delete network-interface.

Command Syntax

```
network-interface  IFNAME
network-interface  IFNAME  vlan  VLAN_ID
network-interface  IFNAME  port  IFNAME
network-interface  (gps|prc)
no network-interface
```

Parameters

IFNAME	The name of a physical interface
gps	GPS interface
prc	SMA/SMB or external interfaces
Vlan	Vlan configuration applicable for g8275.1 profile
VLAN_ID	VLAN ID 1-4094
Port	Physical port

Command Mode

PTP Clock Port Mode

Applicability

This command was introduced in OcNOS-SP version 4.0.

Example

```
#configure terminal
(config)#ptp clock profile g8275.1
(config-ptp-clk)#clock-port 1
(config-clk-port)#network-interface xe2
(config-clk-port)#exit
(config-ptp-clk)#clock-port 2
(config-clk-port)#network-interface xe3 vlan 2
(config-clk-port)#exit
(config-ptp-clk)#clock-port 3
(config-clk-port)#network-interface gps
(config)#ptp clock profile g8275.2
(config-ptp-clk)#clock-port 1
(config-clk-port)#network-interface vlan1.2 port xe1
```

number-ports

Use this command to set the number of PTP ports on the instance. If the number of ports is larger than one, the clock is configured as a boundary clock, otherwise it's an ordinary clock.

Use no form of this command to set default value 1.

Command Syntax

```
number-ports <1-31>
no number-ports
```

Parameters

<1-31>	The number of PTP ports on this instance.

Command Mode

PTP Clock Mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
#configure terminal
(config)#ptp clock profile g8275.1
(config-ptp-clk)#number-ports 3
```

offset-log-variance

Use the command to specify an offset variance. The offset (scaled logarithmic variance) provides an estimate of the variations of the clock from a linear time scale when it is not synchronized to another clock using the PTP protocol.

Note: Applicable for Non-Ethernet ports for PTP Clock Port mode.

Command Syntax

```
offset-log-variance <0-65535>
no offset-log-variance
```

Parameters

`<0-65535>`	The offset variance when not synchronized.

Command Mode

PTP Clock Mode and PTP Clock Port Mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
#configure terminal
(config)#ptp clock profile g8275.1
(config-ptp-clk)#offset-log-variance 3000
```

Note: Use no form of this command in PTP Clock Mode to set default value 65535.

```
(config-ptp-clk)#clock-port 1
(config-clk-port)#offset-log-variance 2000
```

Note: Use no form of this command in PTP Clock Port Mode to set default value 0x4E5D for clock-port.

priority2

Use this command to set the Priority2 attribute of the local clock (as specified in the IEEE-1588 standard).

Use no form of this command to set default value 128.

Command Syntax

```
priority2 <1-255>
no priority2
```

Parameters

<1-255>	The Priority2 attribute.

Command Modeg

PTP Clock Mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
#configure terminal
(config)#ptp clock profile g8275.1
(config-ptp-clk)#priority2 3
```

ptp clock profile

Use this command to enter PTP Clock Mode and to configure the g8275.1 and g8275.2 profile.

Use no form of this command to delete ptp clock.

Command Syntax

```
ptp (clock) profile (g8275.1|g8275.2)
no ptp (clock) profile (g8275.1|g8275.2)
```

Parameters

g8275.1	PTP time/phase g8275.1 telecom profile
g8275.2	PTP time/phase g8275.2 telecom profile

Command Mode

PTP Clock Mode

Applicability

This command introduced in OcNOS-SP version 4.0.

Example

```
#configure terminal
(config)#ptp clock profile g8275.1
(config-ptp-clk)exit

#configure terminal
 (config)#ptp clock profile g8275.2
 (config-ptp-clk)exit
```

reserved-vlan-base-id

Use this command to set the Reserved VLAN base ID.

Use no form of this command to set default base id 4064.

Command Syntax

```
reserved-vlan-base-id <2-4094>
no reserved-vlan-base-id
```

Parameters

<2-4094>	Base VLAN identifier range.

Command Mode

PTP Clock Mode

Default

Default VLAN base ID is 4064.

Applicability

This command was introduced in OcNOS-SP version 4.0.

Example

```
#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
(config)#
(config)#ptp clock profile g8275.1
(config-ptp-clk)#reserved-vlan-base-id 2
```

servo-history

Use this command to enable servo-history with specified interval.

Use no form of this command to disable servo-history.

Command Syntax

```
servo-history <1-60>
no servo-history
```

Parameters

<1-60>	Enable servo-history in interval of <1-60> mins (default is 15 mins)

Command Mode

PTP Clock Mode

Default

Default interval value is 15 mins.

Applicability

This command was introduced in OcNOS-SP version 4.0.

Example

```
#configure terminal
Enter configuration commands, one per line.End with CNTL/Z.
(config)#
(config)#ptp clock profile g8275.1
(config-ptp-clk)# servo-history 2
```

show ptp clock

Use this command to display a summary of the Precision Time Protocol (PTP) clock status.

Command Syntax

```
show ptp clock (dataset (default|current|parent|time-properties|)|)
```

Parameters

`dataset`	The clock dataset
`default`	The default clock status
`current`	The current clock status
`parent`	The clock status of the parent-clock
`time-properties`	The clock dataset time-properties

Command Mode

Privileged Exec mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
#show ptp clock
PTP Clock Profile             : g8275.1
Holdover Duration             : 120 min
Default Dataset:
  Two Step Flag               : No
  Clock Identity              : B8:6A:97:FF:FE:F5:F4:C4
  Number Of Ports             : 1
  Priority1                   : 128
  Priority2                   : 128
  Slave Only                  : No
  Local Priority              : 128
  Max Steps Removed           : 255
  Domain Number               : 24
  Clock Quality               :
    Clock Class               : 248
    Clock Accuracy            : 254
    Offset ScaledLogVariance  : 65535

Current Dataset:
  Steps Removed               : 0
  Offset From Master          : 0 (0.000 nsec)
  Mean Path Delay             : 0

Parent Dataset:
  Parent Port ID              :
    Clock Identity            : B8:6A:97:FF:FE:F5:F4:C4
```

```
        Port Number               : 0
      Parent Stats                : No
      Observed Parent O.S.L.V     : 65535 (Offset Scaled Log Variance)
      Observed Parent P.C.R.      : 2147483647 (Phase Change Rate)
      Grandmaster Identity        : B8:6A:97:FF:FE:F5:F4:C4
      Grandmaster Priority1       : 128
      Grandmaster Priority2       : 128
      Grandmaster Clock Quality   :
        Clock Class               : 248
        Clock Accuracy            : 38
        Offset ScaledLogVariance  : 65535

    Time Dateset:
      Current UTC Offset Valid    : False
      Current UTC Offset          : 36
      Leap 59                     : False
      Leap 61                     : False

      Time of Day                 : Thu Jan  1 19:52:59 1970
```

show ptp port brief

Use this command to display a summary of PTP ports.

Command Syntax

```
show ptp port brief
```

Parameters

None

Command Mode

Privileged Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
#show ptp port brief
Clock    Intf               Port                    Link
Port     Name               State          Encap    State     Mechanism
-------------------------------------------------------------------------
1        xe2                Master         Eth      Up        1-step E2E
2        xe1                Master         Eth      Up        1-step E2E
```

show ptp port dataset

Use this command to display a summary of PTP ports.

Command Syntax

```
show ptp port (<1-31>|) dataset
```

Parameters

<1-31>	PTP port number

Command Mode

Privileged Exec mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
#show ptp port dataset
Port 1:
  Port State                  : Master
  Port Identity               : B8:6A:97:FF:FE:F5:F4:C4:00:01
  Log Min Delay Req Interval  : -4
  Peer Mean Path Delay        : 0
  Log Announce Interval       : -3
  Announce Receipt Timeout    : 3
  Log Sync Interval           : -4
  Delay Mechanism             : End to end
  Version Number              : 2
  Local Priority              : 128
  Master only                 : False
  Signal Fail                 : False
  Network Interface           : xe0
  Vlan Configured             :
  Description                 : l3
  TTL                         : 64
  DSCP                        : 56
  Unicast Grant Duration      : 300
  Configured delay asymmetry  : 101000000 nsec
  Received Packets            : 0
  Discarded Packets           : 0
  Transmitted Packets         : 99
```

show ptp port peer

Use this command to display a peer summary of PTP ports.

Command Syntax

```
show ptp port (<1-31>|) peer
```

Parameters

<1-31>	PTP port number

Command Mode

Privileged Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
#show ptp port peer
Port 1 (1 peers):
  Peer #0
  IPv4 Address                : 10.1.1.2
  Clock Identity              : e8:c5:7a:ff:fe:2e:63:1c
  Received Announce           : 3297
  Received Sync               : 26523
  Received Delay Response     : 26524
  Received Signalling         : 9
  Transmitted Delay Request   : 26524
  Transmitted Signalling      : 9
```

show ptp port master

Use this command to display a master summary of PTP ports.

Command Syntax

```
show ptp port (<1-31>|) master
```

Parameters

<1-31>	PTP port number

Command Mode

Privileged Exec mode

Applicability

This command was introduced in OcNOS-SP version 4.0.

Example

```
#show ptp port master
Port 1:
  Master #0                   : 10.1.1.2
```

show ptp port slave

Use this command to display a slave summary of PTP ports.

Command Syntax

```
show ptp port (<1-31>|) slave
```

Parameters

<1-31>	PTP port number

Command Mode

Privileged Exec mode

Applicability

This command was introduced in OcNOS-SP version 4.0.

Example

```
#show ptp port slave
Port 1:  Slave #0
     IPv4 Address                : 10.1.1.1
    Clock Identity              : e8:c5:7a:ff:fe:2e:4b:1c
    Delay Mechanism             : End to end
    log Announce Interval       : -3
    log Sync Interval           : -6
    Log Delay Req Interval      : -6
```

show ptp servo

Use this command to display servo information.

Command Syntax

```
show ptp servo
```

Parameters

None

Command Mode

Privileged Exec mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
#show ptp servo
PTP servo status for clock 0
  Servo Config                : Phase Correction
  Servo State                 : Warmup
  Servo State Duration        : 04:26:07
  Servo APTS Mode             : N/A
  Lock Status                 : Unlocked
  Frequency Correction        : 0.000 ppb
  Phase Correction            : 0.000 nsec
  Offset From Master          : 0.000 nsec
  Mean Path Delay             : 0 nsec
  Sync Packet Rate            : 0
  Delay Packet Rate           : 0
```

show ptp servo history

Use this command to display servo history.

Command Syntax

```
show ptp servo history
```

Parameters

None

Command Mode

Privileged Exec mode

Applicability

This command was introduced in OcNOS-SP version 4.0.

Example

```
# OcNOS#show ptp servo history
Time                            Phase Correction        Freq Correction
                                (nsec)                  (pbb)
-----------------------------------------------------------------------
2000 Jan 06 19:15:01            0.000                   0.000
2000 Jan 06 19:17:01            0.000                   0.000
2000 Jan 06 19:19:01            0.000                   0.000
2000 Jan 06 19:21:01            0.000                   0.000
2000 Jan 06 19:23:01            0.000                   0.000
2000 Jan 06 19:25:01            0.000                   0.000
```

show ptp stats

Use this command to display PTP packet statistics.

Command Syntax

```
show ptp stats
```

Parameters

None

Command Mode

Privileged Exec mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
#show ptp stats

clock 0:
  Number of ports             : 32
  Received Packets            : 0
  Discarded Packets           : 0
  Received IPv4 PTP Packets   : 0
  Received IPv6 PTP Packets   : 0
  Received L2 PTP Packets     : 0
  RX Queue Overflows          : 0
  Transmitted Packets         : 346

Port 1:
  Received Packets            : 0
  Discarded Packets           : 0
  Transmitted Packets         : 34
```

slave-only

Use this command to set a clock to a slave-only clock.

Use no form of this command to unconfigure this option.

Command Syntax

```
slave-only
no slave-only
```

Parameters

None

Command Mode

PTP Clock Mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
#configure terminal
(config)#ptp clock profile g8275.1
(config-ptp-clk)#slave-only
```

source-address

Use this command to set source-address as linklocal for g.8275.2 profile.

Use no form of this command to unconfigure this command.

Command Syntax

```
source-address ipv6 linklocal
no source-address ipv6 linklocal
```

Parameters

None.

Command Mode

PTP Clock Port mode

Applicability

This command introduced in OcNOS-SP version 4.0.

Example

```
OcNOS#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
(config)#
(config)#ptp clock profile g8275.2
(config-ptp-clk)#clock-port 1
(config-clk-port)# source-address ipv6 linklocal
```

Transport

Use this command to set transport type as ipv4 or ipv6. Applicable for g.8275.2 profile.

Use no form of this command to unconfigure transport-type.

Command Syntax

```
transport (ipv4|ipv6)
no transport
```

Parameters

Ipv4	IPv4 Transport Type
Ipv6	IPv6 Transport Type

Command Mode

PTP CLock Port mode

Applicability

This command introduced in OcNOS-SP version 4.0.

Example

```
#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
(config)#
(config)#ptp clock profile g8275.2
(config-ptp-clk)#clock-port 1
(config-clk-port)#transport ipv6
```

ttl

Use this command to set ttl value. Applicable for g.8275.2 profile.

Use no form of this command to set default value 64.

Command Syntax

```
ttl VALUE
no ttl
```

Parameters

<1-255>	Setting ttl value (default is 64)

Command Mode

PTP Clock Port mode

Applicability

This command introduced in OcNOS-SP version 4.0.

Example

```
#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
(config)#
(config)#ptp clock profile g8275.2
(config-ptp-clk)#clock-port 1
(config-clk-port)#ttl 2
```

unicast-grant-duration

Use this command to set unicast-grant-duration value. Applicable for g.8275.2 profile. Default is 300.

Use no form of this command to set default value 300.

Command Syntax

```
unicast-grant-duration <60-1000>
no unicast-grant-duration
```

Parameters

<60-1000>	Unicast-grant-duration value (default is 300)

Command Mode

PTP Clock Port mode

Applicability

This command introduced in OcNOS-SP version 4.0.

Example

```
#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
(config)#
(config)#ptp clock profile g8275.2
(config-ptp-clk)#clock-port 1
(config-clk-port)#unicast-grant-duration 70
```

SECTION 13 Synchronous Ethernet

Synchronous Ethernet Configuration Guide

Contents

This guide contains these chapters:

CHAPTER 1 Configuring Synchronous Ethernet

This chapter shows how to configure Synchronous Ethernet. This chapter shows two scenarios in selecting a frequency source:

- Using quality level
- Using priority

Topology

In the topology shown in Figure 1-117, SW2 can select a clock source from SW1 or SW3. The selection is based on quality level or priority.

Note: We can enable SyncE on the physical interfaces which can be L2, L# or member port of the LAG.

Figure 1-117: Selecting a Frequency Source

Using Quality Level

In the procedure below, SW1 and SW3 are both configured as output sources, with SW1 having quality level QL_PRC and SW3 having quality level QL_SSU_A. SW2 is configured to accept a frequency from either SW1 or SW3. Because quality level is used as the clock selection criteria (the default setting), SW2 chooses SW1 as the frequency source.

SW1

`#configure terminal`	Enter configure mode.
`(config)#synce`	Enter configure Synchronous Ethernet mode.
`(config-synce)#synchronization option 1`	Set the synchronization network type.
`(config-synce)#exit`	Exit configure Synchronous Ethernet mode.
`(config)#interface eth6`	Configure interface eth6.
`(config-if)#switchport`	Configure eth6 as a layer 2 port.
`(config-if)# bridge group 1`	Configure the interface to be part of bridge 1.
`(config-if)#synce`	Enter interface Synchronous Ethernet mode.
`(config-if-synce)#mode synchronous`	Configure synchronous mode.
`(config-if-synce)#output-source`	Configure the interface as an output source.
`(config-if-synce)#quality-level QL_PRC`	Assign the quality level as PRC.
`(config-if-synce)#exit`	Exit interface Synchronous Ethernet mode.
`(config-if)#exit`	Exit interface mode.

SW2

`(config)#interface eth9`	Configure interface eth9.
`(config-if)#switchport`	Configure eth9 as a layer 2 port.
`(config-if)# bridge group 1`	Configure the interface to be part of bridge 1.
`(config-if)#synce`	Enter interface Synchronous Ethernet mode.
`(config-if-synce)#mode synchronous`	Configure synchronous mode.
`(config-if-synce)#input-source 2`	Configure the interface as an input source with priority 2.
`(config-if-synce)#exit`	Exit interface Synchronous Ethernet mode.
`(config-if)#exit`	Exit interface mode.
`(config)#interface eth10`	Configure interface eth10.
`(config-if)#switchport`	Configure eth10 as a layer 2 port.
`(config-if)# bridge group 1`	Configure the interface to be part of bridge 1.
`(config-if)#synce`	Enter interface Synchronous Ethernet mode.
`(config-if-synce)#mode synchronous`	Configure synchronous mode.
`(config-if-synce)#input-source 2`	Configure the interface as an input source with priority 2.
`(config-if-synce)#exit`	Exit interface Synchronous Ethernet mode.
`(config-if)#exit`	Exit interface mode.

SW3

`(config)#interface eth6`	Configure interface eth6.
`(config-if)#switchport`	Configure eth1 as a layer 2 port.
`(config-if)# bridge group 1`	Configure the interface to be part of bridge 1.
`(config-if)#synce`	Enter interface Synchronous Ethernet mode.
`(config-if-synce)#mode synchronous`	Configure synchronous mode.
`(config-if-synce)#output-source`	Configure the interface as an output source.
`(config-if-synce)#quality-level QL_SSU_A`	Assign the quality level as SSU_A.
`(config-if-synce)#exit`	Exit interface Synchronous Ethernet mode.
`(config-if)#exit`	Exit interface mode.

Validation

SW1

1. Verify the Synchronous Ethernet details.

```
#Verify the output source.
#show synce output-sources
Interface Name  : eth6
Link State      : Up
QL Configured   : QL_PRC
QL Operational  : QL_PRC
```

SW2

1. Verify the input source.

```
#
Interface Name          : eth9

Hold-off Timer Running  : No
```

2. Verify the Synchronous Ethernet details.

```
#
# show synce de
Equipment Clock         : EEC-option1
Interface Name          : eth9
ESMC Status             : OK
Is-selected-Source      : YES
QL                      : QL_PRC
SyncE Clock State       : Locked
DPLL Clock State        : Locked
Synce State Duration    : 00:02:25
Selected-Clk-Src-ID     : 256
```

SW3

1. Verify the Synchronous Ethernet details.

```
#
#show synce de
```

```
Equipment Clock          : EEC-option1
SyncE Clock State        : Free-run
DPLL Clock State         : Free-run
```

2. Verify the output source on SW3.

```
#
Interface Name  : eth6
Link State      : Up
QL Configured   : QL_SSU_A
QL Operational  : QL_SSU_A
```

Note: Use "`show synce stats`" to check the counter statistics and use "`clear synce stats`" to clear the counters. Show esmc counters changed to show synce stats.

Using Priority

In the procedure below, SW1 and SW3 in Figure 1-117 are both configured as output sources, with SW1 having priority 2 and SW3 having priority 1. SW2 is configured to accept a frequency from either SW1 or SW3. Because quality level is not used as the clock selection criteria (an explicit setting), SW2 chooses SW3 (with the higher priority) as the frequency source.

SW1

`#configure terminal`	Enter configure mode.
`(config)#synce`	Enter configure Synchronous Ethernet mode.
`(config-synce)#synchronization option 1`	Set the synchronization network type.
`(config-synce)#clock-selection mode ql-disabled`	Disable quality level checking.
`(config-synce)#exit`	Exit configure Synchronous Ethernet mode.
`(config)#interface eth6`	Configure interface eth6.
`(config-if)#switchport`	Configure eth6 as a layer 2 port.
`(config-if)#bridge group 1`	Configure the interface to be part of bridge 1
`(config-if)#synce`	Enter interface Synchronous Ethernet mode.
`(config-if-synce)#mode synchronous`	Configure synchronous mode.
`(config-if-synce)#output-source`	Configure the interface as an output source.
`(config-if-synce)#quality-level QL_PRC`	Assign quality level as PRC.
`(config-if-synce)#exit`	Exit interface Synchronous Ethernet mode.
`(config-if)#exit`	Exit interface mode.

SW2

`#configure terminal`	Enter configure mode.
`(config)#synce`	Enter configure Synchronous Ethernet mode.
`(config-synce)#clock-selection mode ql-disabled`	Disable quality level checking.
`(config-synce)#exit`	Exit configure Synchronous Ethernet mode

(config)#interface eth9	Configure interface eth9.
(config-if)#switchport	Configure eth9 as a layer 2 port.
(config-if)#bridge group 1	Configure the interface to be part of bridge 1
(config-if)#synce	Enter interface Synchronous Ethernet mode.
(config-if-synce)#mode synchronous	Configure synchronous mode.
(config-if-synce)#input-source 2	Configure the interface as an input source with priority 2.
(config-if-synce)#exit	Exit interface Synchronous Ethernet mode.
(config-if)#exit	Exit interface mode.
(config)#interface eth10	Configure interface eth10.
(config-if)#switchport	Configure eth10 as a layer 2 port
(config-if)#bridge group 1	Configure the interface to be part of bridge 1
(config-if)#synce	Enter interface Synchronous Ethernet mode.
(config-if-synce)#mode synchronous	Configure synchronous mode.
(config-if-synce)#input-source 1	Configure the interface as an input source with priority 1.
(config-if-synce)#exit	Exit interface Synchronous Ethernet mode.
(config-if)#exit	Exit interface mode.

SW3

#configure terminal	Enter configure mode.
(config)#synce	Enter configure Synchronous Ethernet mode.
(config-synce)#synchronization option 1	Configure synchronization network as option 1.
(config-synce)#clock-selection mode ql-disabled	Disable quality level checking.
(config-synce)#exit	Exit configure Synchronous Ethernet mode.
(config)#interface eth6	Configure interface eth6.
(config-if)#switchport	Configure eth6 as a layer 2 port.
(config-if)#bridge group 1	Configure the interface to be part of bridge 1
(config-if)#synce	Enter interface Synchronous Ethernet mode.
(config-if-synce)#mode synchronous	Configure synchronous mode.
(config-if-synce)#output-source	Configure the interface as an output source.
(config-if-synce)#quality-level QL_SSU_A	Assign quality level as SSU_A.
(config-if-synce)#exit	Exit interface Synchronous Ethernet mode.
(config-if)#exit	Exit interface mode.

Validation

SW1

1. Verify the Synchronous Ethernet details.

```
#show synce de
Equipment Clock         : EEC-option1
SyncE Clock State       : Free-run
```

```
DPLL Clock State        : Free-run
Synce State Duration    : 00:39:20
```

2. Verify the output source.

```
#show synce output-sources
Interface Name  : eth6
Link State      : Up
QL Configured   : QL_PRC
QL Operational  : QL_PRC
```

SW2

1. Verify the input source.

```
Interface Name          : eth9
ESMC Status             : OK
Is-selected-Source      : No
QL Configured           : N/A
QL received in ESMC     : QL_PRC
QL Operational          : QL_PRC
Priority                : 2
Hold-off(ms)            : 300
Wait-to-restore(mins)   : 5
Link State              : Up
Signal Fail             : No
External Commands       : None
Clock-source-ID         : 256
WTR Timer Running       : No
Hold-off Timer Running  : No

Interface Name          : eth10
ESMC Status             : OK
Is-selected-Source      : Yes
QL Configured           : N/A
QL received in ESMC     : Ql_SSU_A
QL Operational          : Ql_SSU_A
Priority                : 2
Hold-off(ms)            : 300
Wait-to-restore(mins)   : 5
Link State              : Up
Signal Fail             : No
External Commands       : None
Clock-source-ID         : 256
WTR Timer Running       : No
Hold-off Timer Running  : No
```

2. Verify the Synchronous Ethernet details.

```
# show synce de
Equipment Clock         : EEC-option1
Interface Name          : eth10
ESMC Status             : OK
Is-selected-Source      : YES
QL                      : QL_SSU_A
SyncE Clock State       : Locked
DPLL Clock State        : Locked
```

```
Synce State Duration    : 00:02:25
Selected-Clk-Src-ID     : 256
```

SW3

1. Verify the Synchronous Ethernet details.

```
#show synce de
Equipment Clock         : EEC-option1
SyncE Clock State       : Free-run
DPLL Clock State        : Free-run
Synce State Duration    : 00:39:20
```

2. Verify the output source.

```
#show synce output-sources
Interface Name  : eth6
Link State      : Up
QL Configured   : QL_SSU_A
QL Operational  : QL_SSU_A
```

Synchronous Ethernet Command Reference

Contents

This document contains these chapters:

CHAPTER 1 SyncE Commands

This chapter describes the Synchronous Ethernet configuration commands:

clock-selection mode

Use this command to set whether to use the Quality Level (QL) as a criteria when selecting a clock.

Use the no form of this command to set the QL to its default (`ql-enabled`).

Command Syntax

```
clock-selection mode (ql-enabled|ql-disabled)
no clock-selection
```

Parameters

`ql-enabled`	Use the quality level as a criteria when selecting a clock
`ql-disabled`	Do not use the quality level as a criteria when selecting a clock

Default

The default value is `ql-enabled`.

Command Mode

Synchronous Ethernet mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
(config)#synce
(config-synce)#clock-selection mode ql-enabled

(config-synce)#no clock-selection
```

clock-source-id

Use this command to set the clock source ID for Synchronous Ethernet interface.

Use the no form of this command to unset this value.

Note: Assign the same clock source ID if interfaces are connected to same clock source.

Command Syntax

```
clock-source-id <1-255>
no clock-source-id
```

Parameters

<1-255>	Clock Source ID.

Command Mode

Interface Synchronous Ethernet Mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
#configure terminal
(config)#interface xe1
(config-if)#synce
(config-if-synce)#clock-source-id 1
```

dpll3-select

Use this command to select dpll3 as fixed input 10MHZ-IN.

Use no form of this command to unset this configuration.

Command syntax

```
dpll3-select 10mhz-in
no dpll3-select
```

Command Mode

Interface Synchronous Ethernet mode

Applicability

This command was introduced before OcNOS version 4.0.

Examples

```
(config)#interface eth1
(config-if)#synce
(config-if-synce)#dpll3-select 10mhz-in
```

hold-off

Use this command to set the hold-off time in milliseconds. The hold-off time ensures that short activation of signal fail is not passed to the selection process.

Use the no form of this command to set the default value (300 milliseconds).

Command syntax

```
hold-off <300-1800>
no hold-off
```

Parameters

<300-1800>	Hold-off time in milliseconds

Default

The default value is 300 milliseconds.

Command Mode

Interface Synchronous Ethernet mode

Applicability

This command was introduced before OcNOS version 1.3.

Examples

```
(config)#interface eth1
(config-if)#synce
(config-if-synce)#hold-off 500

(config-if-synce)#no hold-off
```

holdover

Use this command to set Synchronous holdover. Applicable only for 10MHz out interface.

Use no form of this command to disable holdover.

Command Syntax

```
holdover (<0-1440>|)
no holdover
```

Parameters

<0-1440>	Synchronous holdover range in minutes.

Command Mode

Synchronous Ethernet Mode

Default

Default Synchronous holdover is 10 minutes.

Applicability

This command was introduced in OcNOS-SP version 4.0.

Example

```
#configure terminal
(config)#synce
(config-synce)#holdover 2
```

input-source

Use this command to set an input timing source. Synchronization packets are received from this source and sent to the clock selection algorithm.

Use the no form of this command to delete an input source.

Command Syntax

```
input-source <0-255>
no input-source
```

Parameters

<0-255>	Priority: 1 is the highest, 255 is the lowest; 0 means the source will not be considered by the clock selection algorithm

Default

The default value is 0 meaning the interface will not be considered by the clock selection algorithm.

Command Mode

Interface Synchronous Ethernet mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
(config)#interface eth1
(config-if)#synce
(config-if-synce)#input-source 1
```

mode

Use this command to configure the interface as synchronous or non-synchronous:

- Synchronous interfaces extract the frequency of their input signal from synchronization packets and passes them to their internal clocks.
- Non-synchronous interfaces do not participate in the synchronization process.

Use the no form of this command to set the mode to its default (`non-synchronous`).

Command Syntax

```
mode (synchronous | non-synchronous)
no mode
```

Parameters

`synchronous` Synchronous mode

`non-synchronous` Non-synchronous mode

Default

The default value is `non-synchronous`.

Command Mode

Interface Synchronous Ethernet mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
(config)#interface eth1
(config-if)#synce
(config-if-synce)#mode synchronous

(config-if-synce)#no mode
```

output-source

Use this command to use an Ethernet interface as a timing output source.

Use the no form of this command to stop using an Ethernet interface as a timing output source.

Command Syntax

```
output-source
no output-source
```

Parameters

None

Command Mode

Interface Synchronous Ethernet mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
(config)#interface eth1
(config-if)#synce
(config-if-synce)#output-source
```

quality-level

Use this command to set the quality level (QL) for the timing source.

Use the no form of this command unconfigure quality-level on a port.

Command Syntax

```
quality-level QL_VAL
no quality-level
```

Parameters

QL_VAL	Quality level. The quality level you can specify depends on setting of the synce-interface command. See ITU-T Rec. G.781 for details.
QL_PRC	Primary Reference Clock
QL_SSU_A	Types I or V slave clock
QL_SSU_B	Type VI slave clock
QL_SEC	SDH Equipment Clock
QL_DNU	Do not use this signal for synchronization
QL_STU	Synchronized – traceability unknown
QL_ST2	Traceable to stratum 2
QL_ST3E	Traceable to stratum 3E
QL_SMC	Traceable to SONET clock self timed
QL_PROV	Provisionable by the network operator

Command Mode

Interface Synchronous Ethernet mode

Applicability

This command was introduced before OcNOS version 1.3.

Examples

```
(config)#interface eth1
(config-if)#synce
(config-if-synce)#quality-level QL_PRC
```

sync (configure mode)

Use this command to configure Synchronous Ethernet.

This command changes the mode from configure mode to configure Synchronous Ethernet mode and initializes the global Synchronous Ethernet parameters.

Use no form of this command to disable synce.

Command Syntax

```
synce
no synce
```

Parameters

None

Command Mode

Configure mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
(config)#synce
(config-synce)
```

synce (interface mode)

Use this command to enable Synchronous Ethernet for an interface.

This command changes the mode from interface mode to interface Synchronous Ethernet mode.

This command does not automatically start synchronization distribution. You must explicitly give the mode command, specifying the `synchronous` option.

Use the `no` form of this command disable Synchronous Ethernet for an interface.

Command Syntax

```
synce
no synce
```

Parameters

None

Command Mode

Interface mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
(config)#interface eth1
(config-if)#synce
(config-if-synce)#
```

synce debug

Use this command to turn on debugging.

Use the no from of this command to turn off debugging

Command Syntax

```
synce debug (event|recvd|trans)
no synce debug (event|recvd|trans)
```

Parameters

`event`	Enable event debugging
`recvd`	Enable reception debugging
`trans`	Enable transmission debugging

Command Mode

Privileged Exec mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#synce debug event
```

synce-interface

Use this command to enable Synchronous Ethernet for both GPS and 10MHz interfaces as input interfaces. This command changes the mode from interface mode to Synchronous interface Ethernet mode.

Use no form of this command to delete synce interface.

Command Syntax

```
synce-interface (gps | 10mhz-in|ptp)
no synce-interface (gps | 10mhz-in|ptp)
```

Parameters

`gps`	Input interface as GPS
`10mhz-in`	Input interface as 10MHz
`ptp`	PTP interface as input-source

Command Mode

Interface mode

Applicability

This command was introduced in OcNOS-SP version 4.0.

Example

```
(config)#interface eth1
(config-if)#synce-interface gps
(config-synce-if)#
```

synchronization option

Use this command to set the synchronization option for the internal clock that is locked in frequency to an incoming signal.

Use the no form of this command to set the default synchronization option (1).

Command Syntax

```
synchronization option (1 | 2)
no synchronization option
```

Parameters

1	Networks optimized for the 2048 kbit/s hierarchy
2	Networks optimized for the 1544 kbit/s hierarchy that includes the rates 1544 kbit/s, 6312 kbit/s, and 44 736 kbit/s

Default

The default value is 1.

Command Mode

Configure Synchronous Ethernet mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
(config)#synce
(config-synce)#synchronization option 2

(config-synce)#no synchronization option
```

wait-to-restore

Use this command to set the wait-to-restore timer in minutes. The wait-to-restore time ensures that a synchronization source that previously failed is considered by the selection process again only if it is fault free for a certain time.

Use the no form of this command to set the default wait-to-restore time (5 minutes).

Command syntax

```
wait-to-restore <0-12>
no wait-to-restore
```

Parameters

<0-12>	Wait-to-restore time in minutes

Default

The default value is 5 minutes.

Command Mode

Interface Synchronous Ethernet mode

Applicability

This command was introduced before OcNOS version 1.3.

Examples

```
(config)#interface eth1
(config-if)#synce
(config-if-synce)#wait-to-restore 1

(config-if-synce)#no wait-to-restore
```

CHAPTER 2 SyncE Show Commands

This chapter describes the Synchronous Ethernet show commands:

show synce stats

Use this command to display Ethernet Synchronization statistics.

Note: Show esmc counters changed to show synce stats.

Command Syntax

```
show synce stats
```

Parameters

None

Command Mode

Privileged Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
#show synce stats
Interface Name    Status      ESMC Received  ESMC Sent
_____________________________________________________
xe47                OK          1_________________1
xe48                OK          5_________________2
```

show synce details

Use this command to display details of the clock most recently selected by the Clock Selection Algorithm (CSA).

Command Syntax

```
show synce details
```

Parameters

None

Command Mode

Privileged Exec mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
#show synce details
Equipment Clock         : EEC-option1
Interface Name          : eth9
ESMC Status             : OK
Is-selected-Source      : YES
QL                      : QL_PRC
SyncE Clock State       : Locked
DPLL Clock State        : Locked
Synce State Duration    : 00:03:26
Selected-Clk-Src-ID     : 256
```

show synce input-sources

Use this command to display details of all interfaces that are configured as Synchronous Ethernet input sources.

Command Syntax

```
show synce input-sources
```

Parameters

None

Command Mode

Privileged Exec mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
#show synce input-sources
Interface Name          : xe1
ESMC Status             : OK
Is-selected-Source      : YES
QL Configured           : QL_PRC
QL received in ESMC     : QL_PRC
Operational QL          : QL_PRC
Priority                : 1
Hold-off(ms)            : 300
Wait-to-restore(mins)   : 5
Signal Fail             : No
External Commands       : None
Clock-source-ID         : 256
WTR Timer Running       : No
Hold-off Timer Running  : No
```

show sync output-sources

Use this command to display details of all interfaces that are configured as Synchronous Ethernet output sources.

Command Syntax

```
show synce output-sources
```

Parameters

None

Command Mode

Privileged Exec mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
#show synce output-sources
Interface Name  : eth6
Link State      : Up
QL Configured   : QL_PRC
QL Operational  : QL_DNU
```

SECTION 14 sFlow

Sampling Flow Configuration Guide

Contents

This document contains this chapter:

CHAPTER 1 sFlow Configuration

This chapter provides the steps for configuring Sampled Flow (sFlow).

sFlow is the standard for monitoring high-speed switched and routed networks. The sFlow monitoring system consists of an sFlow Agent which is embedded in a switch or router and an sFlow Collector.

The sFlow agent samples packets as well as polling traffic statistics for the device it is monitoring. The packet sampling is performed by the switching/routing device at wire speed. The sFlow agent forwards the sampled traffic statistics in sFlow PDUs as well as sampled packets to an sFlow collector for analysis.

Note: sFlow egress sampling for multicast, broadcast, or unknown unicast packets is not supported.

The sFlow agent uses the following forms of sampling:

- Sampling packets: samples one packet out of a defined sampling rate. This sampling is done by hardware at wire speed.
- Sampling counters: polls interface statistics such as generic and Ethernet counters at a defined interval.

You must enable the sFlow feature and collector before enabling sFlow sampling on an interface.

You cannot globally enable sFlow sampling monitoring on all interfaces with a single command. Instead you must enable sFlow sampling on the required interfaces individually.

sFlow feature is supported on physical interface as well as LAG interface. Configuring sampling on a LAG interface will enable the same on all member ports part of that LAG interface.

Topology

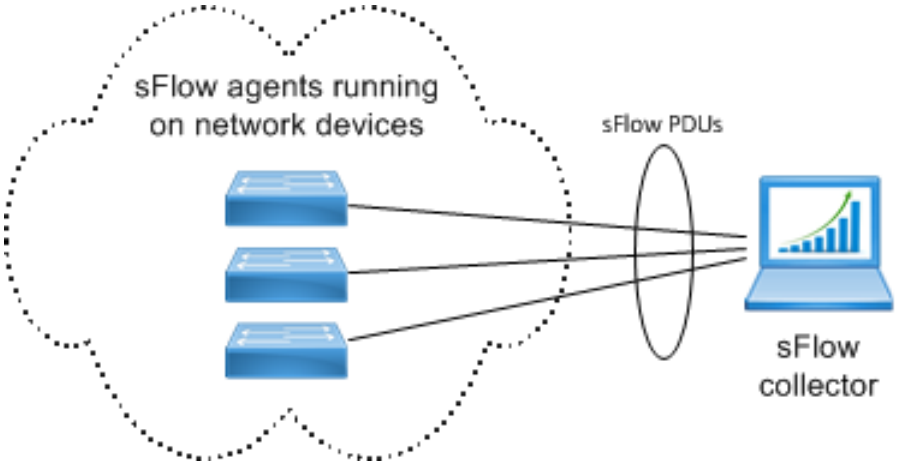

Figure 1-118: Basic sFlow topology

Configuration

sFlow Agent

`#configure terminal`	Enter configure mode.
`(config)#feature sflow`	Enable the sFlow feature.

(config)#sflow collector 2.2.2.2 port 6343 receiver-time-out 0 max-datagram-size 200	Configure the sFlow collector
(config)#interface xe1	Enter interface mode
(config-if)#sflow poll-interval 5	Set the counter poll Interval on the interface.
(config-if)#sflow sampling-rate 1024 direction ingress max-header-size 200	Set the sFlow sampling interval on the interface in ingress directions.
(config-if)#sflow sampling-rate 1024 direction egress max-header-size 120	Set the sFlow sampling interval on the interface in egress directions.
(config-if)#sflow enable	Start packet sampling on the interface
(config-if)#end	Exit interface and configure mode.

Validation

```
#show sflow detail
sFlow Feature: Enabled
sFlow Version: 5
sFlow Global Information :
Agent     IP: 10.10.26.132

Sampling Flow Command Reference

Contents

This document contains this chapter:

CHAPTER 1 sFlow Commands

This chapter describes the Sampled Flow (sFlow) commands.

clear sflow statistics

Use this command to clear sFlow sampling-related counters such as the number of packets sampled and the number of counters sampled.

Command Syntax

```
clear sflow statistics (interface IFNAME|)
```

Parameters

IFNAME	Interface name

Default

None

Command Mode

Exec mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#clear sflow statistics
```

debug sflow

Use this command to display sFlow debugging messages.

Command Syntax

```
debug sflow (all|agent|sampling|polling|)
```

Parameters

`all`	Debug all (agent,sampling,polling)
`agent`	Debug sFlow agent
`sampling`	Debug sFlow sampling
`polling`	Debug sFlow polling

Default

By default, debug command is disabled.

Command Mode

Exec mode and Configure mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#debug sflow all
#debug sflow agent

#configure terminal
(config)#debug sflow agent
```

feature sflow

Use this command to enable the sFlow feature.

Use the no form to disable the sFlow feature.

Command Syntax

```
feature sflow
no feature sflow
```

Parameters

None

Default

By default, sFlow feature is disabled.

Command Mode

Configure mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
(config)#feature sflow
```

sflow agent-ip

Use this command to set the agent IP address for receivers.

Use the no form of this or remove an agent IP address.

Command Syntax

```
sflow agent-ip A.B.C.D
no sflow agent-ip
```

Parameter

A.B.C.D	IPv4 address

Default

The default IP address is zero (0).

Command Mode

Configure mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#configure terminal
(config)#sflow agent-ip 10.0.0.12
```

sflow collector

Use this command to configure the collector details such as the collector IPv4 address, port number, receiver time-out and datagram size.

Use the no form of this command to disable the sFlow collector.

Command Syntax

```
sflow collector A.B.C.D port <1024-65535> receiver-time-out <0-2147483647>
  max-datagram-size <200-9000>
no sflow collector (A.B.C.D port <1024-65535> receiver-time-out <0-2147483647> max-
  datagram-size <200-9000> |)
```

Parameter

A.B.C.D	Collector IPv4 address
<1024-65535>	Collector UDP Port number. The standard sFlow UDP Port : 6343
<0-2147483647>	Receiver time out value in seconds. Zero means no timeout. Upon timeout, value collector information is removed, stopping any ongoing sampling.
<200-9000>	Maximum datagram size in bytes that can be sent Collector

Default

By default, sFlow collector is disabled. Default port number is 6343.

Command Mode

Configure mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#configure terminal
(config)#sflow collector 2.2.2.2 port 1111 receiver time-out 30 max-datagram-
size 500

(config)#no sflow collector
```

sflow enable

Use this command to enable or disable sampling on an interface after giving the sflow sampling-rate command on the same interface.

Command Syntax

```
sflow enable
no sflow enable
```

Default

By default, sFlow sampling is disabled.

Parameters

None

Command Mode

Interface mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
(config)#interface xe1
(config-if)#sflow sampling-rate 1024 direction ingress max-datagram-size 200
(config-if)#sflow enable
(config-if)#no sflow enable
```

sflow poll-interval

Use this command to configure the sFlow counter polling interval. Any change in the polling interval restarts ongoing polling of existing data source interfaces, if any.

Use the no form of this command to disable the sFlow counter polling interval.

Command Syntax

```
sflow poll-interval <5-60>
no sflow poll-interval <5-60>
```

Parameters

<5-60>	Interface counter. Polling interval in seconds

Default

By default, sFlow counter polling interval is disabled.

Command Mode

Interface mode

Applicability

This command was introduced before OcNOS version 1.3.

Examples

```
#configure terminal
(config)#interface xe1
(config-if)#sflow poll-interval 25
(config-if)#no sflow poll-interval 25
```

sflow rate-limit

Use this command to set the CPU rate limit in packets per second.

Use the no form of this command to set the CPU rate limit to its default (0).

Command Syntax

```
sflow rate-limit <2000-100000>
no sflow rate-limit
```

Parameters

<2000-100000>	Rate limit in packets per second

Default

The default rate limit is zero (0).

Command Mode

Configure mode

Applicability

This command was introduced before OcNOS version 1.3.

This command is not available on Qumran platforms.

Examples

```
#configure terminal
(config)#sflow rate-limit 5000
```

sflow sampling-rate

Use this command to set the sampling rate on an interface. Any change in the sampling rate restarts the ongoing sampling of existing data-source interfaces, if any.

Use the no form of this command to disable the sFlow sampling rate.

Note: Packets to CPU is rate limited. In case of unknown unicast, rate limit is applied to such packets as well as sampled data packets.

Command Syntax

```
sflow sampling-rate <1024-1073741823> direction (ingress | egress) max-header-size
  <128-256>
```

```
no sflow sampling-rate <1024-1073741823> direction (ingress | egress) max-header-
  size <128-256>
```

Parameters

`<1024-1073741823>`	
	Sampling rate
`direction`	The direction of sampling an interface:
`ingress`	Ingress traffic
`egress`	Egress traffic
`<128-256>`	Maximum header size in bytes

Default

By default, sFlow sampling rate is disabled.

Command Mode

Interface mode

Applicability

This command was introduced before OcNOS version 1.3.

Examples

```
#configure terminal
(config)#interface xe1
(config-if)#sflow sampling-rate 1024 direction ingress max-header-size 200
(config-if)#no sflow sampling-rate 1024 direction ingress max-header-size 200
```

show sflow

Use this command to display sFlow agent configuration along with statistics for all interfaces.

Command Syntax

```
show sflow (brief | detail)
```

Parameters

`brief`	Display configuration parameters on interfaces along with sampling rate and poll interval.
`detail`	Same as `brief` along with configured and default attributes and values of sFlow agent, sFlow collector, and sampling information.

Default

None

Command Mode

Exec mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#show sflow
sFlow Feature: Enabled
sFlow Version: 5
sFlow Global Information :
Agent     IP: 10.12.16.38
Collector IP: 10.12.16.17      Port:  6343
Maximum Datagram Size(bytes): 200
Receiver timeout(sec)        : 0

sFlow Port Detailed Information:
Interface  Packet-Sampling           Packet-Sampling            Counter-Polling         Maximum Header
                 Rate                     Count               Interval       Count        Size(bytes)
           Ingress      Egress       Ingress      Egress       (sec)                     Ingress     Egress
---------  ----------------------   ----------------------  ----------------------   -------------------
xe1            1024            0            0            0           6            3     128            0

#
#show sflow brief
sFlow Feature: Enabled
Collector IP: 10.12.16.17      Port:  6343
Maximum Datagram Size(bytes): 200
Receiver timeout(sec)        : 0

sFlow Port Configuration:
Interface   Status               Sample Rate               Counter-Polling
            Ingress    Egress    Ingress      Egress       Interval(sec)
---------   ------------------   ----------------------   ---------------
xe1       Enabled    Disabled         1024            0      6
```

Table 1-72: Show sflow output

Entry	Description
sFlow feature	Shows whether sFlow is enabled or disabled.
sFlow Version	Displays the sFlow version. Version 5 is the current global standard.
sFlow Global Information	Global Information consists of the Agent IP address, Collector IP, Port number, Maximum Datagram Size, and the Receiver timeout.
Agent IP	IPv4 address of this switch/router.
Collector IP	IPv4 address of the sFlow collector server.
Port	Port number on the sFlow collector server. Standard is port 6343.
Maximum Datagram Size	The maximum size of the datagrams sent by the agent
Receiver timeout	The number of seconds between each sampling – zero means sample continuously.
sFlow Port Interface	The interface of this switch/router on which sFlow is running (e.g. xe1/1).
Packet-Sampling Rate	the number of packets received or transmitted before a sample is taken.
Packet-Sampling Count	The number of sample packets that have been sampled on both the ingress and egress of the interface.
Counter-Polling	Shows the amount of time between polling samples and the count of the total number of polling samples taken.
Maximum Header Size	The maximum header size for both the ingress and egress of the interface.

show sflow interface

Use this command to display the sFlow configuration for the input interface.

Command Syntax

```
show sflow interface IFNAME
```

Parameters

IFNAME	Interface name

Default

None

Command Mode

Exec mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

Note: For information on the output values of this command, see the show sflow command.

```
#show sflow interface xe1
sFlow feature: Enabled
sFlow Version: 5
sFlow Global Information :
Agent     IP: 10.10.26.104
Collector IP: 10.12.16.18      Port:  6343
Maximum Datagram Size(bytes): 200
Receiver timeout(sec)        : 0

sFlow Port Detailed Information:
Interface  Packet-Sampling           Counter-Polling           Maximum Header
           Rate         Count        Interval(sec) Count       Size(bytes)
---------  -----------------------   ------------------------  --------------
xe1              1024            0           6           41      128
```

show sflow statistics

Use this command to display sFlow counter information.

Command Syntax

```
show sflow statistics (interface IFNAME|)
```

Parameters

IFNAME	Interface name.

Default

None

Command Mode

Exec mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

Note: For information on the output values of this command, see the show sflow command.

```
#show sflow statistics

sFlow Port Statistics:
Interface  Packet-Sampling   Counter-Polling
                Count              Count
---------  ---------------   ---------------
xe1                     0                19
```

SECTION 15 Quality of Service

Quality of Service Configuration Guide

Contents

This document contains these chapters.

CHAPTER 1 Quality of Service (QoS)

This chapter contains a general overview of QoS functionality and terminology.

QoS Functionality

Quality of Service (QoS) can be used to give certain traffic priority over other traffic. Without QoS, all traffic in a network has the same priority and chance of being delivered on time. If congestion occurs, all traffic has the same chance of being dropped. With QoS, specific network traffic can be prioritized to receive preferential treatment. In turn, a network performs more predictably, and utilizes bandwidth more effectively.

QoS is based on DiffServ architecture, which stipulates that individual packets be classified upon entry into a network. Classification information can be carried in the Layer-3 IP packet header or the Layer-2 frame. IP packet headers carry the information using 6-bits from the deprecated IP type of service (TOS) field. Layer-2 802.1Q frames carry the information using a 2-byte Tag Control Information field. All switches and routers accessing the Internet depend on class information to give the same forwarding treatment to packets with the same class information, and give different treatment to packets with different class information. A packet can be assigned class information, as follows:

- End hosts or switches along a path, based on a configured policy
- Detailed packet examination, expected to occur nearer to the network edge, to prevent overloading core switches and routers
- A combination of the above two techniques

Class information can be used by switches and routers along a path to limit the amount of allotted resources per traffic class. Per-hop behaviour is an individual device’s behaviour when handling traffic in the DiffServ architecture. An end-to-end QoS solution can be created if all devices along a path have consistent per-hop behaviour.

Quality of Service (QoS) provides preferential treatment to specific traffic, possibly at the expense of other traffic. Without QoS, Qumran offers best-effort service to each packet, however, this may cause unpredictable network behaviour. Implementing QoS in a network makes performance more predictable and bandwidth utilization more effective.

QoS design in Qumran complies with IETF-DiffServ and IEEE 802.1p standards. A typical QoS model deployment is based on the following elements:

- The packet received on customer edge port will be assigned to a QoS service. The service is assigned based on the packet header information.
- The QoS service defines the packet's internal QoS handling (i.e. traffic class/queue and drop precedence/color) and optionally the packet's external QoS marking, through either the IEEE 802.1p User Priority or the IP header DSCP field.
- Qumran provides end-to-end QoS behavior by providing consistent QoS treatment to the traffic within the network core based on packet's IEEE 802.1 or DSCP marking.
- Qumran can modify the assigned service of the packets if a packet stream exceeds the ingress configured rate by marking drop precedence and remarking packet's IEEE 802.1p or DSCP at the egress.
- Qumran incorporates the required QoS features to implement network-edge, as well as, network-core devices.
- Qumran provides flexible mechanisms to classify packets into different service levels.
- Service application mechanism is based on eight egress priority queues per port.
- The packet Priority fields can be remarked to reflect the QoS assignment on L2 and L3 networks.

  Note: Packet priority remarking on an MPLS network is not supported.

Terminology

Following is a brief description of terms and concepts used to describe QoS.

ACL

Access control lists (ACLs) classify traffic with the same characteristics.

CoS Value

Class of Service (CoS) is a 3-bit value used to classify the priority of Layer-2 frames upon entry into a network. QoS classifies frames by assigning priority-indexed CoS values to them, and gives preference to higher-priority traffic.CoS values range from zero to seven, seven being the highest priority.

DSCP Value

DSCP Value Differentiated Services Code Point (DSCP) is a 6-bit value used to classify the priority of Layer-3 packets upon entry into a network. DSCP values range from 0 to 63, 63 being the highest priority, 0 being best-effort traffic.

Classification

Classification distinguishes one kind of traffic from another by examining the fields in the packet. Classification is enabled only if QoS is globally enabled on the switch. By default, QoS is globally disabled, thus, no classification occurs. Classification occurs on an ingress physical port. Classification can be based on QoS ACLs, or class maps and policy maps.

Policing

Policing can occur on ingress interfaces. Policer limits the bandwidth consumed by a traffic flow with the results given to the marker. The two types of policers:

- Individual: QoS applies the bandwidth limits specified in the policer, separately, to each matched traffic class. An individual policer is configured within a policy map.

Marking

Marking determines how to handle a packet when it is out of profile. It assesses the policer and the configuration data to determine the action required for the packet, and then handles the packet using one of the following methods:

- Let the packet through without modification
- Drop the packet

Marking can occur on ingress and egress interfaces.

Queuing

Queuing maps packets to a queue. Each egress port can accommodate up 8 queues, prioritized as 0 lowest and 7 highest. The tagged packet incoming priority can be mapped to one of the 8 queues obtained from the filtering

mechanism result. The untagged packet priority is also obtained from the filtering mechanism result. After the packets are mapped to a queue, they are scheduled.

Scheduling

Scheduling forwards or conditions packets using one of the following methods:

- Strict Priority-Based (SP), in which any high-priority packets are first transmitted. Lower-priority packets are transmitted only when the higher-priority queues are empty. A problem may occur when too many lower-priority packets are not transmitted. Strict Priority will be operating on the remaining bandwith available for the Port
- WFQ (Weighted Fair Queuing) weight-based scheduling – In this scheduling, some weight based bandwidth is allocated to all queues. In this scheduling, egress traffic will be served based on the configured weight distribution.
- Combination of WFQ and SP, the Remaining Bandwidth will be scheduled in the strict order for the SP Queues. The Remaining Bandwidth will be scheduled in the WFQ mode for WFQ Queues.

Class Map

A class map names and isolates specific traffic from other traffic. The class map defines the criteria used to match against a specific traffic flow to classify it further. The criteria can include:

- Matching the access group defined by the ACL
- Matching a specific list of CoS, DSCP, Exp and etc.

If there is more than one type of traffic to be classified, another class map can be created under a different name. After a packet is matched against the class-map criteria, it is further classified using a policy map.

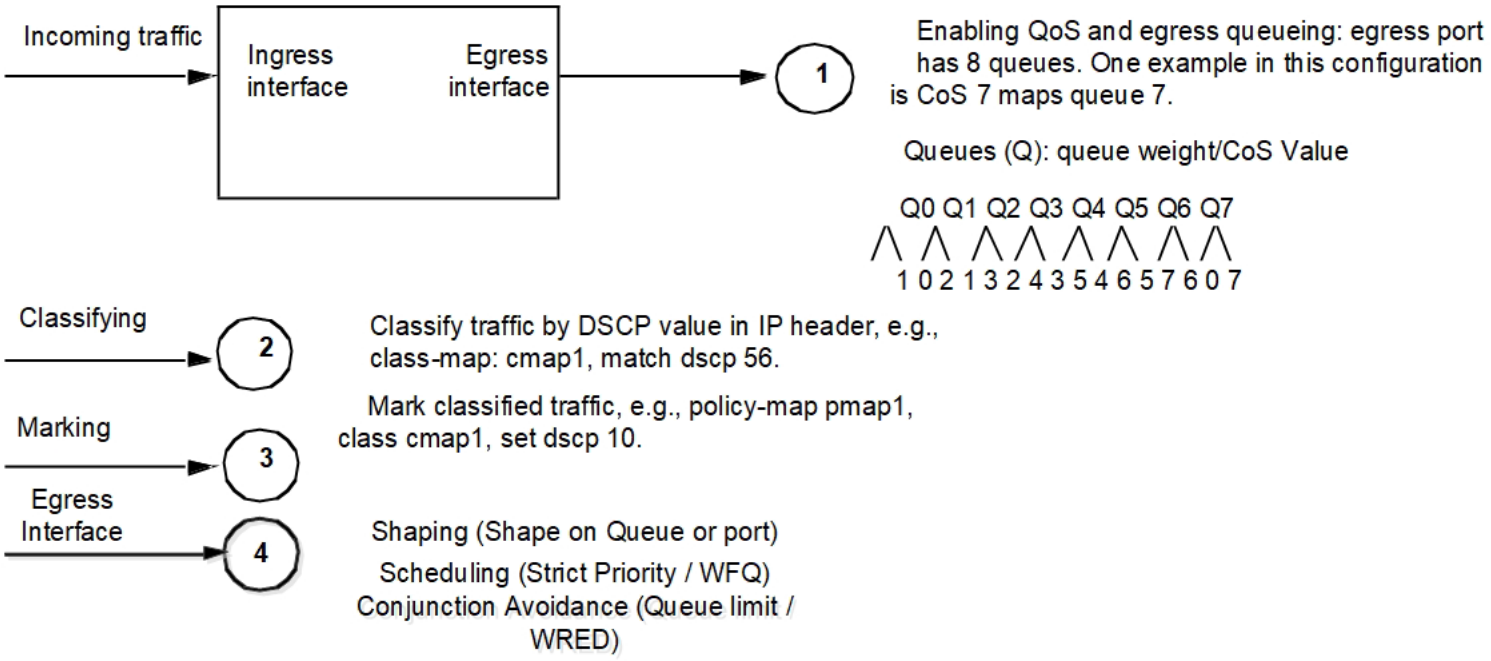
Policy Map

A policy map specifies on which traffic class to act. This can be implemented as follows:

- Set a specific CoS or DSCP value in the traffic class.
- Specify the traffic bandwidth limitations for each matched traffic class (policer) and the action to take (marking) when the traffic is out of profile.

Policy maps have the following attributes:

- A policy map can contain Maximum 256 class-map per policy-map, each with different match criteria and policers.
- A separate policy-map class can exist for each type of traffic received through an interface.
- There can be only one policy map per interface per direction. The same policy map can be applied to multiple interfaces and directions.
- Before a policy map can be effective, it must be attached to an interface.



QoS model

This section explains the implementation and configuration details of QoS:

Traffic types

Data — Packets can be network-to-network traffic or traffic from CPU. Network-to-network packets are considered data traffic and QoS parameters can be applied on data traffic.

Control — Packets to and from the CPU are considered as control traffic. Incoming control traffic is prioritized based on ingress map and are sent to their own designated CPU queues. Each CPU queue has a fixed rate limit to guard the CPU. Outgoing control traffic will always be sent on highest priority queue (Q7) on the data port.

Setting packet header QoS fields

The device supports modifying the packets header IEEE 802.1p user priority or IP-DSCP.

Packet QoS Attributes

Every data packet is assigned a set of QoS attributes that can be modified in several stages of the ingress pipeline engine.

The ingress pipeline engine also contains a QoS Remark option for L3 traffic that can modify the initial QoS attributes of the packet.

Color and Drop Precedence relation: Green has the lowest drop precedence, Yellow has a higher drop precedence, and Red has the highest drop precedence. See Table 1-73.

Table 1-73: Packet QoS attributes

QoS Parameter	Description
TC (Traffic Class or queue)	This is the priority level assigned to the packet. When the transmission engine queries the packet, it uses this field to select the appropriate priority queue
DP (Drop Precedence or color)	The transmission engine uses this field for congestion resolution. Packets with higher drop precedence are more likely to be discarded in the event of congestion. By default, packets with red color will be dropped by a Qumran even if there is no congestion. Disabling red packet drop is configurable per device. In case of L2 packet, DEI 0 will be marked to color green and DEI 1 will be marked to color yellow. In case of L3 packet, AFx1 will be marked as green while both AFx2 and AFx3 will be marked as yellow (where x=1,2,3).

CHAPTER 2 Configuring a QoS Policy-map

The following section explains the configuration of basic infrastructure to apply QoS treatment on the ingress interface.

Ingress QoS treatment can be achieved by two types of configuration.

- Policy-map configuration
- Profile mapping configuration

This section explains policy-map configuration method. QoS feature must be enabled to configure policy-maps.

This infrastructure contains two entities - class-map and policy-map. Class-map holds the match criteria and class-maps can be bound to policy-map to configure QoS treatment for the matching traffic.

Creating a QoS class-map

A Class-map contains the matching criteria for the traffic. Class-maps with no match criteria will match all the data traffic.

Class-maps support the following match criteria: vlan, inner vlan, cos, inner cos, dscp, precedence, layer4 tcp/udp port, exp, Ether-type, or ACL.

Class-map can be of two types, match-any or match-all type. By default class-map is of match-all type. For match-all class-maps, only the traffic that qualifies all match criteria configured in class-map will take QoS action. For match-any class-maps, traffic qualifying any one of the configured match criteria will take QoS action.

Class-maps can be created once the QoS feature is enabled.

Use the following command to create a class-map:

```
class-map (type qos|) (match-any|match-all|) NAME
```

This command will create a class-map entity that can be configured with one or more match criteria.

Class-map can be of two types:

1. Empty class-map: Class-map with no matching criteria is called empty class. Empty class will classify all the traffic coming on the port on which the policy containing empty class will be applied.
2. Non-empty class-map: Class-map with matching criteria is called non-empty class. It will classify the traffic according to the given matching criteria.

User can always add/delete/modify the matching criteria of the class-map. User is not allowed to make a non-empty class as empty class if the class is attached to a policy-map. User has to remove the class from policy-map to modify the matching criteria. User is allowed to add matching criteria to an empty class attached to a policy-map.

Use the following commands to add match criteria:

```
match vlan WORD
match vlan inner WORD
match cos WORD
match cos inner WORD
match dscp [WORD | af11 | af12 | af13 | af21 | af22 | af23 | af31 | af32 | af33 | af41 | af42 | af43 | cs1 | cs2 | cs3 | cs4 | cs5 | cs6 | cs7 | default | ef]
match precedence [WORD | critical | flash | flashoverride | immediate | internet | network | priority | routine]
match mpls experimental topmost WORD
match ip rtp WORD
match ethertype WORD
match layer4 (tcp|udp|any) (source-port|destination-port) WORD
```

```
match access-group NAME
```

An example of creating a class-map with match VLAN configuration is shown below:

```
(config)#qos enable
(config)#class-map n1-class-10
(config-cmap-qos)#match vlan 10
(config-cmap-qos)#exit
```

Notice that data traffic with an outer VLAN value of 10 will be matched for QoS treatment.

Creating a QoS policy-map

Policy-maps can be configured with multiple class-maps with each class-map configured with policing or other supported actions.

Use the following command to create a policy-map:

```
policy-map (type qos|) NAME
```

This command will create a policy-map entity in which one or more class-map entities can be bound.

Binding a class-map to a policy-map

In order to apply QoS treatment to traffic that matches the criteria configured in a class-map, the class-map must be bound to the policy-map entity, then QoS treatment actions can be configured on that node.

Use the following command to bind a class-map to a policy-map:

```
class (type qos|) NAME
```

This command will create a class node for class-map unique to the policy-map. This class node can then be configured with QoS treatment actions.

There are two types of actions, `police` and set.

- Police actions can be used to control the rate of traffic flow and is explained in the next section.
- Set actions can be used to set internal priority or packet priority.

Use the following commands to add set actions:

```
set (dscp (<0-63>| af11| af12| af13| af21| af22| af23| af31| af32| af33| af41| af42|
af43| cs1| cs2| cs3| cs4| cs5| cs6| cs7| default| ef ))
set cos <0-7>
set queue <0-7>
```

An example of creating a policy-map and binding a class-map to it with the `set` action is shown below:

```
(config)#policy-map n1-police-10
(config-pmap-qos)#class n1-class-10
(config-pmap-c-qos)#set cos 3
(config-pmap-c-qos)#exit
(config-pmap-qos)#exit
```

In case of multiple class-maps, implicit priority of class-maps will be decided based on the following the type of class-map as shown:

match-all > match-any > default class-map

If all class-maps are of type match-all, the class-map with the higher number match criteria will have higher priority. If the class-maps have the same number of match criteria, then the behavior can be unpredictable if traffic matches both class-map criteria. In such cases, class-maps can be explicitly prioritized using the priority command.

priority <1-1000>

An example of configuring priority per class-map is shown below:

```
(config)#policy-map p1
(config-pmap-qos)#class c1
(config-pmap-c-qos)#priority 2
```

A higher the value means higher priority, and user defined priority is always higher prioritized over implicit priority.

If the match criteria is ACL, different hardware resources will be used. Therefore, configuring match ACL class-map and other non-ACL match classes in a single policy is not allowed because if a policy-map with two class-maps (one with ACL match criteria and one with some other match criteria) are allowed (configured in different hardware resource groups), traffic matching both match criteria can take actions of both class-maps if the actions are not conflicting but since statistics are common and can be read once (hardware limitation), statistics will be displayed for one matching criteria only.

Assumptions and limitations

DSCP and precedence matches are mutually exclusive and can't be part of same class-map.

Each rule of an ACL is matched independently, so ACL matches are allowed to be configured only on match-any type class-map. If the configured matches on class-maps bound to and interface via policy-map are not mutually exclusive, there are chances of multiple class-maps matching a single stream of traffic. In this case, implicit priority of the class-map based on number of rules decides which class-map the traffic will hit. When implicit priority is the same for class-maps, their behavior will be random, and the user is expected to configure class priority in such a case.

Binding a QoS policy-map

Policy-map configuration is effective only when it is bound to a supported ingress interface. Use the following command to bind a policy-map to an interface:

```
service-policy type qos input NAME
```

Notice that `NAME` represents the name of the qos policy-map.

Note: A QoS TCAM group must be enabled before binding a policy-map to an interface. Refer to the "*hardware-profile filters (Qumran)*" and "*show hardware-profile filters show (Qumran)*" sections in the *Command Reference Guide* for more information about the hardware filter groups.

An example of binding a policy-map to an interface is shown below:

```
(config)#hardware-profile filter qos-ext enable
(config)#interface xe1
(config-if)#service-policy type qos input n1-police-10
(config-if)#exit
```

In this example, traffic with VLAN value 10 received on interface `xe1` is matched by `class-map` configuration, and traffic will be set with internal and packet priority (cos) 3 (as shown in the previous example).

Note: For an ACL match configuration, ingress-l2-ext/ingress-ipv4-ext/ingress-ipv6 TCAM group must be enabled based on ACL type.

When the class-map is configured with match ACL, only the `police` action is supported – `set` actions are not supported.

CHAPTER 3 Traffic Policing

Traffic policing can be achieved by using a policy-map based method. Policy-map based configurations allow the flexibility to police the traffic per-port and a set of other matching criteria:

- VLAN (outer vlan and inner vlan)
- CoS (outer cos and inner cos)
- DSCP
- Topmost EXP
- Ether-typ
- Precedence
- TCP or UDP port
- ACL

Note: Qumran supports rate limiting of ingress traffic. Rate limiting egress traffic is not supported.

Applying Traffic Policing Parameters Using a policy-map

Policy-map based traffic policing can be achieved by binding policy-map on the interface in ingress direction. A policy-map is associated with two sections. One is class-map which will have match criteria configured. Other is police configuration to apply traffic policing on the matching traffic on the policy-map bound port in ingress direction (see Chapter 2, *Configuring a QoS Policy-map*).

Traffic policing determines the rate of ingress traffic that is allowed per port (traffic that matches the configuration in the class-map).

Note: Qumran supports two types of policing:

- Single rate three color traffic rate limiting (RFC 2697).
- Two rate three color traffic rate limiting (RFC 4115).

Single rate or two rate operations are in compliance with the RFCs mentioned.

Note: Packets marked with color red are dropped by default in Qumran devices. This default behavior can be modified with global command to disable red packet drop. However, traffic policing and storm control will not work if red packet drop is disabled.

For more information about color, refer to the Packet QoS Attributes section.

Configuration Considerations

- Policy map based rate limiting is supported only for ingress traffic.
- Only one policy-map of same type can be bound on an interface.
- One policy-map can have up to 256 class-maps.
- CIR and EIR configuration should be in same format. Example, if one of them is configured in percentage, other also should be configured in percentage.
- Minimum configurable rate is 22 kilobits per second.
- Minimum burst size supported is 1 kilo bytes and maximum burst size supported in 4161 kilo bytes.

Configuring Traffic Policing

The following section shows how to configure policing on an interface. Refer to Chapter 2, *Configuring a QoS Policy-map* for configuring policy-maps.

Note: Policer action must be configured on the class node to achieve traffic policing for matching traffic.

Use the following command to configure a policer for Qumran MX:

```
police (colour-blind | colour-aware |) (cir) (<1-720000000> (kbps|mbps|gbps) | percent
<1-100>) ((eir (<1-720000000> (kbps|mbps|gbps) | percent <1-100>)|) ((bc) <1-4161>
(kbytes|mbytes|ms|us)|) ((be) <1-4161> (kbytes|mbytes|ms|us)|))
```

Use the following command to configure a policer for Qumran AX:

```
police (colour-blind | colour-aware |) (cir) (<1-500000000> (kbps|mbps|gbps) | percent
<1-100>) ((eir (<1-500000000> (kbps|mbps|gbps) | percent <1-100>)|) ((bc) <1-4161>
(kbytes|mbytes|ms|us)|) ((be) <1-4161> (kbytes|mbytes|ms|us)|))
```

- For Qumran MX, the configuable rate range is 22kbps to 720gbps.
- For Qumran AX, the configuable rate range is 22kbps to 500gbps.

An example of creating a policy-map and binding a class-map to it with police action is shown below:

```
(config)#qos enable
(config)#class-map n1-class-10
(config-cmap-qos)#match vlan 10
(config-cmap-qos)#exit
(config)#policy-map n1-police-10
(config-pmap-qos)#class n1-class-10
(config-pmap-c-qos)#police cir 10 mbps eir 20 mbps
(config-pmap-c-qos)#exit
(config-pmap-qos)#exit
(config)#hardware-profile filter qos-policer enable
(config)#interface xe1
(config-if)#service-policy type qos input n1-police-10
(config-if)#exit
```

In the following example, traffic with vlan ID 10 received on interface `xe1` will be policed to a total of 30 mbps with 10 mbps of traffic being marked green, and 20 mbps of traffic marked yellow, any remaining traffic will be dropped at ingress.

Example configuration for color aware police:

```
(config-pmap-c-qos)#police colour-aware cir 10 mbps eir 20 mbps
```

With this configuration, if traffic with vlan ID 10 (with CFI bit set) is received on interface `xe1` it is “policed” to a total of 20 mbps only because the traffic will be treated as yellow and will be subjected only to the EIR bucket.

Displaying Rate Limiting Policies

Use the following commands to verify the configuration and statistics.

- `show policy-map` – This command displays the configuration of policy map.
- `show policy-map interface INTERFACE-NAME` – This command displays the policy-map details on the interface along with statistics of how many packets and bytes matches and how many packets and bytes are dropped due to policer.
- `show policy-map statistics type qos` – This command displays the statistics of matched packets and bytes and dropped packets and bytes per class-map in table format.

Note: Packets dropped by the policer are counted in policy-map drops, as well as in queue red drops because the hardware doesn't support policer action to directly drop the packet. Packets that need to be dropped are marked red and are dropped at the queue.

Use the following command to obtain QoS statistics:

```
qos statistics
```

Use the following command to clear QoS statistics.

```
clear qos statistics
```

Drop counters verification

Drop counters with drop reason can be verified globally using the following command:

```
#show hardware-discard-counters
+---------------------------------+---------+------------+------------+
| Registers                                 | Core 0     | Core 1     |
+---------------------------------+---------+------------+------------+
IQM_QUEUE_ENQ_DISCARDED_PACKET_COUNTER        1596100
   Reason: DP_LEVEL_STATUS                    Y
EGQ_PQP_DISCARD_UNICAST_PACKET_COUNTER        59807
   Reason: SRC_EQUAL_DEST_INT                 Y
```

CHAPTER 4 Rate Limiting BUM Traffic

To prevent the CPU from getting flooded with Broadcast, Unknown Unicast, and Multicast (BUM) traffic, rate limiting can be applied at the ingress interface. This configuration is called “storm control” and is independent of the QoS feature, and can be configured directly on the interface in the ingress direction.

Configuring per port rate limiting for BUM traffic

BUM rate limiting can be configured on the interface via following command:

```
storm-control (broadcast|multicast|dlf) (level LEVEL | <0-1000000000> (kbps|mbps|gbps))
```

The `broadcast` option is for broadcast traffic, `multicast` option is for multicast traffic and `dlf` (Destination Lookup Failure) option is for unknown unicast traffic.

There are two ways to configure the rate limiting information. One is in percentage and the other is in absolute values. Use the level option to configure in percentage format where the link speed is used for rate calculation. Percentage value can be configured with up to four fractional digits in order to support kbps level rate limiting on 100 gbps ports, and the Absolute configuration option uses the input rate in kbps, mbps, or gbps.

An example of BUM rate limiting is shown below:

```
(config)#interface xe1
(config-if)#switchport
(config-if)#storm-control dlf 2 mbps
(config-if)#exit
```

In the configuration above, unknown unicast traffic received on `xe1` will be rate limited to 2 mbps.

Note: Packets marked with color red are dropped by default by Qumran devices. This default behavior can be modified with global command to disable red packet drop. However, traffic policing and storm control will not work if red packet drop is disabled

Displaying BUM rate limit information

Use the following command to verify BUM rate limit configuration:

```
show storm-control (INTERFACE-NAME|)
```

Note: Drop statistics for BUM rate limiting is not supported on Qumran.

CHAPTER 5 Ingress Traffic Processing

Qumran can process packets based on the priority information of the packet. During the packet processing, there are several opportunities to influence the processing by the following configurations:

1. Derive internal priority and drop precedence from the packets IEEE 802.1p (PCP) value and drop eligibility indicator (DEI) value. The Priority Code Point (PCP) is a 3-bit field within an 802.1Q tagged frame that is used to convey the internal priority of the frame and DEI is a single bit that is used to convey the drop precedence of the frame.

   Note: The PCP field was formerly called 802.1p.

2. Derive internal priority and drop precedence from the packets DSCP value.
3. Force modification of internal priority and drop precedence using user defined ingress mapping profile.
4. Force the internal priority value based on classification configured using policy maps. This is used for setting a specific priority for L2, L3 or L4 traffic flow.
5. Packet priority and drop precedence will be based on PCP and DEI values for the traffic received on switch ports. Similarly, packet priority and drop precedence will be based on DSCP value for the IPv4 traffic received router ports. For MPLS traffic on label switched interface, packet priority is based on topmost label's EXP value.
6. When trust level on switch ports is modified to trust DSCP values, packet priority and drop precedence for IPv4 traffic will be based on DSCP value.
7. Assign internal priority to untagged traffic on switch port with port level untagged priority configuration.

Mapping Inbound Packet Priorities to Internal Priorities

Priority and drop precedence information is collected from various portions of the packet header:

- If a tagged packet is received on a switch port, derive a priority value from PCP and drop precedence DEI value.
- If a tagged packet is received on a switch port on which trust level is set to DSCP, derive the priority value from DSCP bits. Drop precedence will be derived from DEI bit value.
- If an untagged packet is received on a switch port, assign priority value based on port level untagged priority configuration.
- If an untagged packet is received on a switch port on which trust level is set to DSCP, derive the drop precedence value from DSCP bits.
- If IPv4 packet is received on a router port, derive a priority value and drop precedence by decoding the DSCP bits.
- If MPLS packet is received on a label switched port, derive a priority value and drop precedence by decoding EXP bits.
- The derived values for PCP and DSCP are mapped to a default map.

CHAPTER 6 Modifying Internal Priority at Ingress

After the packet priority is recognized as PCP, DSCP or EXP values, priority queue and drop precedence will be determined by one of the following methods:

- Default ingress decode mappings are configured as explained in "Chapter 9, *Default QoS Mappings*."
- Global ingress mapping profiles are available for modification to configure non-default values on a Qumran device as explained in "Chapter 10, *Configuring QoS*". Following are the global ingress profiles affecting priority queues and drop precedence configuration:

  `qos profile cos-to-queue default` – Configuration in this profile allows modifying default mapping of PCP to priority queue globally.

  `qos profile dscp-to-queue default` – Configuration in this profile allows modifying default mapping of DSCP to priority queue and drop precedence globally.

  `qos profile exp-to-queue default` – Configuration in this profile allows modifying default mapping of EXP to priority queue and drop precedence globally.
- User-defined ingress decode mapping profiles can be created and bound to port to override the global configuration:

  `qos profile cos-to-queue NAME` – Configuration in this profile allows creating user-defined mapping of PCP to priority queue and can be bound to port to take effect.

  `qos profile dscp-to-queue NAME` – Configuration in this profile allows creating user-defined mapping of DSCP to priority queue and drop precedence and can be bound to port to affect.
- User-defined PCP to TC profile map can be bound to VPLS instance or per-VLAN-based attachment circuit and this mapping will override the profiles mapping bound to port or the global mapping profile.
- User-defined PCP to TC profile map can be bound to VPWS VLAN based attachment circuits and this mapping will override the profile mapping bound to port or the global mapping profile.
- User-defined PCP to TC profile map can be bound to registration entries for provider edge ports and this mapping will override the profile mapping bound to port or the global mapping profile.
- QoS policy-maps can be configured as explained in "Chapter 2, *Configuring a QoS Policy-map*" with set queue action and bound to an ingress port will override the priority queue configuration for the traffic that matches the policy-map configuration. Policy-map configured with `policer` action resulting in color marking will override the drop precedence on the traffic as per configuration.
- Internal priority for untagged traffic received on switch ports will be set to zero by default.
- Untagged traffic can be assigned with a non-default priority queue with port level configuration: `qos untagged-priority <0-7>` – This configuration assigns priority queue for untagged traffic received on the configured switch port.

CHAPTER 7 Remarking Packet Priority at Ingress

Apart from altering the internal priority and drop precedence, Qumran device allows modification of packet priority for PCP and DSCP values by one of the following methods:

- Configuration of ingress dscp-to-queue mapping profile allows the modification of DSCP value of the packet. This mapping is applicable only to IPv4 traffic on router port.
- QoS policy-maps can be configured with set CoS and set DSCP actions which will modify PCP or DSCP value of the packet, respectively. Set CoS action is applicable on switch ports and tagged packets. Set DSCP action is applicable on router port where IPv4 traffic is received on the port. Remarking DSCP through policy-map configuration will override the mapping profile remarking.

Note: Qumran does not support encoding EXP value from packet priority of tagged (PCP) or IPv4 traffic (DSCP) through ingress processing. EXP value encoding is supported only through egress processing.

Note: Refer Chapter 10, *Configuring QoS* for Remarking configuration.

CHAPTER 8 Remarking Packet Priority at Egress

In Qumran, tagged traffic PCP value on switch port and IPv4 traffic DSCP value on router port can be remarked through egress processing. When either the remark CoS or remark DSCP command is enabled on the egress port, one of the following remarkings takes place:

- Default egress encode mappings are configured as explained in “Chapter 9, *Default QoS Mappings*".
- Global egress mapping profiles are available for modification to configure non-default values on a Qumran device as explained in “Chapter 10, *Configuring QoS*”. Following are the global egress profiles affecting packet priority on traffic at egress:

  `qos profile queue-color-to-cos default` — Configuration in this profile allows modifying default mapping of internal priority and drop precedence to packet priority (PCP) globally.

  `qos profile dscp-to-dscp default` — Configuration in this profile allows modifying default mapping of DSCP and drop precedence to packet priority (DSCP) globally.

- User-defined egress encode mapping profiles can be created and bound to egress port to override the global configuration:

  `qos profile queue-color-to-cos NAME` — Configuration in this profile allows creating user-defined mapping of internal priority and drop precedence to packet priority (PCP) and can be bound to egress port to take effect.

  `qos profile dscp-to-dscp NAME` — Configuration in this profile allows creating user-defined mapping of DSCP and drop precedence to packet priority (DSCP) and can be bound to egress port to take effect.

Qumran supports encapsulation mapping profile to mark EXP values derived from DSCP values for IPv4 traffic and internal priority and drop precedence for tagged traffic through egress processing. EXP value encapsulation will be determined by one of the following methods:

- Default egress encapsulation mappings are configured as explained in “*Default QoS Mappings*.”
- Global egress EXP encapsulation mapping profile is available for modifying DSCP value to EXP encapsulation value for IPv4 traffic, and internal priority and drop precedence values to EXP encapsulation for tagged traffic. The command: `qos profile exp-encp default,` allows configuration of L3 DSCP to EXP mapping, and L2 queue, color to EXP mapping globally.
- User-defined egress EXP encapsulation mapping profiles can be created and bound to egress label switched port to override the global configuration: `qos profile exp-encap NAME` — configuration in this profile allows creating user-defined mapping of L3 DSCP to EXP and L2 queue, color to EXP encapsulation values and can be bound to an egress label switched port to take effect on network edge devices (Ingress LER).

CHAPTER 9 Default QoS Mappings

If a user defined profile map is not created or applied to ingress or egress traffic, Qumran uses a default map to assign PCP, DSCP, EXP priority, and drop precedence values. The following tables describe the default QoS mapping values:

Ingress decode mapping table:

- PCP, DEI-to-TC and DP table
- DSCP-to-TC and DP table
- EXP-to-TC and DP table

Egress encode mapping table:

- TC and DP-to-PCP table
- DSCP, DP-to-DSCP table
- EXP encapsulation table

Table 9-74 lists the default PCP, DEI-to-TC, and DP mappings.

Table 9-74: Default PCP, DEI-to-TC and DP

PCP (CoS)	drop eligibility (DE)	Traffic class (queue)	Drop precedence (color)
0 (000)	0	0	Green
0 (000)	1	0	Yellow
1 (001)	0	1	Green
1 (001)	1	1	Yellow
2 (010)	0	2	Green
2 (010)	1	2	Yellow
3 (011)	0	3	Green
3 (011)	1	3	Yellow
4 (100)	0	4	Green
4 (100)	1	4	Yellow
5 (101)	0	5	Green
5 (101)	1	5	Yellow
6 (110)	0	6	Green
6 (110)	1	6	Yellow
7 (111)	0	7	Green
7 (111)	1	7	Yellow

Table 9-75 lists the default TC and DP-to-PCP mappings. This table is effective when egress remarking is enabled.

Table 9-75: Default TC and DP-to-PCP

Traffic class (queue)	Drop precedence (color)	Priority (CoS/PCP)	Drop eligibility (CFI)
0	Green	0	0
0	Yellow/red	0	1
1	Green	1	0
1	Yellow/red	1	1
2	Green	2	0
2	Yellow/red	2	1
3	Green	3	0
3	Yellow/red	3	1
4	Green	4	0
4	Yellow/red	4	1
5	Green	5	0
5	Yellow/red	5	1
6	Green	6	0
6	Yellow/red	6	1
7	Green	7	0
7	Yellow/red	7	1

Note: Table information with red color is applicable only when red packet drop is disabled on the device. Otherwise, red packets are dropped by default.

Table 9-76 lists the default DSCP-to-TC, DP mappings..

Table 9-76: Default DSCP-to-TC and DP

DSCP	Traffic class (queue)	Drop precedence (color)

CHAPTER 10 Configuring QoS

The configuration process involving several commands is described in the following chapter.

Configuring Ingress QoS Procedures

Following section explains the configuration details involved to achieve the ingress QoS treatment as explained in "Chapter 6, *Modifying Internal Priority at Ingress*" and "Chapter 7, *Remarking Packet Priority at Ingress*."

The configuration steps involved are described below:

- Configuring trust level on switch ports
- Configuring internal priority for untagged traffic on switch ports
- Configuring ingress decode mapping profile
- Binding ingress decode mapping profile
- Configuring policy-map to modify internal or packet priority

Configuring trust level on switch ports

Switch ports support two trust levels. By default, trust level is based on PCP value. However, trust level based on DSCP value is configurable per port.

Trust level to DSCP value can be configured through the command:

```
trust dscp
```

When trust DSCP is configured on the port, internal priority will be derived from DSCP value of IPv4 packet based on default `dscp-to-queue` profile configuration. Drop precedence for untagged traffic will be derived from DSCP value of IPv4 packet based on `default dscp-to-queue` profile configuration. For tagged traffic, drop precedence will continue to be based on DEI bit on the packet.

Configuring internal priority for untagged traffic on switch ports

For tagged traffic, internal priority will be derived from PCP value of the packet. Untagged traffic will not carry PCP value and are assigned with internal priority zero by default. Internal priority can be assigned to untagged traffic with following port level configuration:

```
qos untagged-priority <0-7>
```

With untagged priority configured on switch port, internal priority will be selected for untagged traffic based on the configured value.

An example of the configuration is shown below:

```
(config)#interface xe1
(config-if)#switchport
(config-if)#qos untagged-priority 3
(config-if)#exit
```

In the example configuration, untagged traffic received on xe1 will be assigned with internal priority 3 and will be transmitted out of queue 3 at egress port.

Configuring Ingress Decode Mapping Profile

In order to modify the priority and drop precedence values used within the device, user-defined decode mapping profiles can be created or global decode mapping profile contents can be modified.

Three types of decode mapping profiles are supported based on packet priority encoded in tagged IPv4 and in MPLS traffic.

Configuring PCP-to-TC Mapping Profile

User-defined profile can be created or global profile can be modified for PCP-to-TC through the following command:

```
qos profile cos-to-queue (NAME | default)
```

Inside this command PCP-to-TC mapping can be configured using the values:

```
cos <0-7> queue <0-7>
```

Here, CoS is the PCP value and the queue value is the traffic-class being configured.

An example of the configuration is shown below:

```
(config)#qos profile cos-to-queue profile1
(config-ingress-cos-map)#cos 3 queue 4
(config-ingress-cos-map)#cos 2 queue 1
(config-ingress-cos-map)#exit
```

Note: This mapping profile is applicable only to switch ports.

Configuring DSCP-to-TC, DP, DSCP Mapping Profile

User-defined profiles can be created or global profiles can be modified for DSCP-to-TC, DP, and DSCP using the following command:

```
qos profile dscp-to-queue (NAME | default)
```

Inside this command DSCP-to-TC, DP, and DSCP mapping can be configured using the command:

```
dscp <0-63> queue <0-7> (color (green | yellow | red)|) (dscp <0-63>|)
```

An example configuration is shown below:

```
(config)#qos profile dscp-to-queue profile2
(config-ingress-dscp-map)#dscp 8 queue 2
(config-ingress-dscp-map)#dscp 25 queue 4 color yellow
(config-ingress-dscp-map)#exit
```

Note: This mapping profile is applicable only on router ports. However, the default mapping profile is applicable on switch ports as well, if trust level on the switch port is set to DSCP.

Ingress stage remarking of DSCP values can be achieved by configuring the output DSCP in the command, however, this remarking can be overwritten by policy-map based remarking or by egress remarking.

Configuring EXP-to-TC, DP Mapping Profile

Global profile can be modified for EXP-to-TC and DP through the following command:

```
qos profile exp-to-queue default
```

Inside this command, PCP-to-TC mapping can be configured using the command:

```
exp <0-7> queue <0-7> (color (green | yellow | red)|)
```

An example configuration is shown below:

```
(config)#qos profile exp-to-queue default
(config-ingress-exp-queue-map)#exp 3 queue 4 color yellow
(config-ingress-exp-queue-map)#exp 2 queue 1
(config-ingress-exp-queue-map)#exit
```

Note: This mapping profile is applicable only on label-switched router ports.

Binding Ingress Decode Mapping Profile

User-defined mapping profiles will be effective only when they are bound to ingress ports or any services.

User-defined profiles can be bound to port using the command:

```
qos map-profile (cos-to-queue | dscp-to-queue) NAME
```

An example of binding user-defined map to port is shown below:

```
(config)#interface xe1
(config-if)#switchport
(config-if)#qos map-profile cos-to-queue profile1
```

PCP-to-TC decode profiles can be bound to VPLS service instances or attachment circuits. Profile binding to these services can be achieved using the commands:

```
vpls-qos map-profile cos-to-queue NAME
vc-qos map-profile cos-to-queue NAME
```

An example of binding a PCP-to-TC mapping profile to a VPLS service is shown below:

```
(config)#mpls vpls vpls1 1
(config-vpls)#vpls-qos map-profile cos-to-queue cq-profile-1
```

An example of binding a PCP-to-TC profile to an attachment circuit is shown below:

```
(config)#interface xe1
(config-if)#switchport
(config-if)# mpls-vpls MPLS-VPLS service-template VPLS-10
(config-if-vpls)#vc-qos map-profile cos-to-queue cq-profile-2
```

Profile configured on the VPLS service is effective for all attachment circuits associated with VPLS service. However, if a profile is bound to an attachment circuit, then that profile takes higher priority for that attachment circuit.

Traffic received on VPLS service will be affected by QoS treatment by configurations in the following order:

1. Set queue through policy-map configuration. Refer below section for details.
2. PCP-to-TC profile configuration bound to attachment circuit.
3. PCP-to-TC profile configuration bound to VPLS service.
4. PCP-to-TC profile configuration bound to ingress port.
5. PCP-to-TC profile configuration.

Configuring Policy-map to Modify Internal or Packet Priority

QoS policy-map frame work can be used to modify the internal priority or remark the packet priority. For policy-map configuration, refer to “Chapter 2, *Configuring a QoS Policy-map*.” Set action has following two options:

- Modify internal priority - Internal priority or traffic class can be set using the command set queue <0-7> and this command will modify only the internal priority and the configuration is not carried forward to next device.
- Remark packet priority - Packet priority can be set at the ingress processing through set cos <0-7> and set dscp <0-63> to modify PCP value for tagged traffic received on switch port and DSCP value for IPv4 traffic received on router port. Both commands implicitly modify internal priority. Value for internal priority is derived from cos-to-queue profile bound to switch port and DSCP-to-queue profile bound to router port. If profile is not explicitly bound on the interface, internal priority will be derived from default cos-to-queue profile or default dscp-to-queue profile based on interface type. On VLAN interface, set cos will update only internal priority if the traffic is routed. Even if the traffic is routed to another VLAN interface, set cos will not set the packet priority on newly constructed VLAN header and it will be 0 or subject to egress remarking configuration. If traffic is switched, then set cos on VLAN interface will update both internal priority and packet priority. Qumran doesn't support remarking on MPLS traffic.

Configuration example for modifying traffic class is shown below:

```
(config)#policy-map p-1
(config-pmap-qos)#class c-1
(config-pmap-c-qos)#set queue 5
(config-pmap-c-qos)#exit
```

The commands `set cos` and `set dscp` can be configured similarly.

Configuring Egress QoS Procedures

Following section explains the configuration details involved to achieve the egress QoS treatment as explained in "Chapter 8, *Remarking Packet Priority at Egress*."

Configuration steps involved are described below:

- Configuring egress remarking
- Configuring egress encode mapping profile
- Binding egress encode mapping profile
- Configuring and binding EXP encapsulation profile

Configuring Egress Remarking

Qumran supports remarking through egress processing. Remarking is configurable separately for tagged traffic and IPv4 traffic. Remarking can be enabled on the device through global configuration or per interface configuration. Commands provide the flexibility to configure enable remarking globally but selectively disable on certain ports or enable only on certain ports.

An example of enabling egress remarking globally is shown below:

```
(config)#qos remark cos
```

This configuration takes effect on all egress switch ports and tagged traffic transmitted through the port will be egress remarked.

The syntax of the command is:

```
qos remark (cos | dscp)
```

An example of enabling egress remarking on an egress port is shown below:

```
(config)#interface xe1
(config-if)#switchport
(config-if)# qos remark cos enable
```

This configuration takes effect on xe1 and tagged traffic transmitted through xe1 will be egress remarked.

The syntax of the command is:

```
qos remark (cos | dscp) (enable | disable)
```

Configuring Egress Encode Mapping Profile

In order to modify the default encoding packet priority values when remarking is enabled on the device, a user-defined encode mapping profile can be created or global decode mapping profile content can be modified.

Two types of encode mapping profiles are supported in Qumran device.

Configuring TC, DP-to-PCP mapping profile

User-defined profile can be created or global profile can be modified for TC, DP-to-PCP using the following command:

```
qos profile queue-color-to-cos (NAME | default)
```

In this profile mode TC, DP-to-PCP mapping can be configured through the command:

```
queue <0-7> (color (green | yellow)| red) cos <0-7>
```

Here, the queue value is the traffic class, color is the drop precedence, and CoS is the PCP value to be remarked.

An example of a configuration is shown below:

```
(config)#qos profile queue-color-to-cos profile1
(config-egress-cos-map)#queue 4 cos 3
(config-egress-cos-map)#queue 1 color yellow cos 2
(config-egress-cos-map)#exit
```

Note: This mapping profile is applicable only on switch ports.

Configuring DSCP, DP to DSCP mapping profile

User-defined profiles can be created or global profiles can be modified for DSCP, DP-to-DSCP using the following command:

```
qos profile dscp-to-dscp (NAME | default)
```

Inside this profile mode DSCP, DP-to-DSCP mapping can be configured using the command:

```
dscp <0-63> (color (green | yellow)| red) dscp <0-63>
```

A configuration example is shown below:

```
(config)#qos profile dscp-to-dscp profile2
(config-egress-dscp-map)#dscp 8 dscp 7
(config-egress-dscp-map)#dscp 24 color yellow dscp 30
(config-egress-dscp-map)#exit
```

Note: This mapping profile is applicable only on router ports.

Note: When ingress DSCP-to-TC, DP, or DSCP profiles with ingress DSCP remarking is bound to an ingress router port, remarked DSCP values will be input for egress DSCP and DP-to-DSCP profiles on the egress interface.

An example of this case is shown below:

```
(config)#qos profile dscp-to-queue profile1
(config-ingress-dscp-map)#dscp 10 queue 3 dscp 24
```

If this profile is bound to ingress router port, then traffic with DSCP 10 will be set with internal priority 3 and DSCP will be remarked to 24 at ingress stage.

```
(config)#qos profile dscp-to-dscp profile2
(config-egress-dscp-map)#dscp 24 dscp 30
```

If the above profile is bound to egress router port, then the mapping entry will match the traffic with remarked DSCP 24 and will effectively update the DSCP value to 30 while egressing the traffic. As a result, traffic with DSCP value 10 will be remarked to DSCP value 30.

Binding egress encode mapping profile

For user-defined mapping profiles to work, they must be bound to egress ports and egress remarking must be enabled.

User-defined profiles can be bound to ports using the following command:

```
qos map-profile (queue-color-to-cos | dscp-to-dscp) NAME
```

An example of binding a user-defined map to a port is shown below:

```
(config)#interface xe1
(config-if)#qos map-profile dscp-to-dscp profile1
```

TC and DP-to-PCP encode profiles can be bound to a VPLS service instance or attachment circuit. Profile binding to these services can be achieved using the following commands:

```
vpls-qos map-profile queue-color-to-cos NAME
vc-qos map-profile queue-color-to-cos NAME
```

An example of binding PCP-to-TC mapping a profile to a VPLS service is shown below:

```
(config)# mpls-vpls MPLS-VPLS service-template VPLS-10
(config-vpls)#vpls-qos map-profile queue-color-to-cos qc-profile-1
```

An example of binding TC, DP-to-PCP profile to attachment circuit is shown below:

```
(config)#interface xe1
(config-if)#switchport
(config-if)#mpls-vpls vpls1 service-template st1
(config-if-vpls)#vc-qos map-profile queue-color-to-cos qc-profile-2
```

QoS egress remarking treatment on VPLS service has multiple configurations available and the priority of configuration is similar to the one explained in “Binding Ingress Decode Mapping Profile”.

Configuring and Binding EXP Encapsulation Profile

When a packet enters an MPLS network side from access side, the MPLS label will be encapsulated to the packet. Qumran supports inheriting packet priority to MPLS header from DSCP values for IPv4 traffic. For tagged traffic, packet priority is inherited by the MPLS header from the traffic class and drop precedence.

Qumran supports both global EXP encapsulation mapping profile and user-defined EXP encapsulation mapping profiles per egress port.

User-defined profiles can be created or global profile can be modified for EXP encapsulation using the following command:

```
qos profile exp-encap (NAME | default)
```

Inside this profile mode, DSCP to EXP mapping for L3 traffic and queue, color to EXP mapping for L2 traffic can be configured using the following ranges:

```
l3 dscp <0-63> exp <0-7>
l2 queue <0-7> (color (green|yellow|red)|) exp <0-7>
```

An example of binding a user-defined map to an egress port of ingress LER is shown below:

```
(config)#interface xe1
(config-if)#label-switching
(config-if)#qos map-profile exp-encap profile1
```

Note: This profile is applicable only on network facing ports of the ingress LER device.

CHAPTER 11 Displaying QoS Information

The following QoS information can be displayed:

- QoS Configuration Information – QoS configuration such as qos mapping profiles, class-maps and policy-maps can be verified by using show commands.
- QoS Packet and Byte Statistics – count of packets and bytes matching the match criteria configured in class-maps bound to ingress ports through policy-maps can be displayed when QoS statistics is enabled.

Displaying QoS Configuration Information

The QoS configurations that can be displayed are listed below:

- Mapping profile configuration
- Class-map configuration
- Policy-map configuration

Display Mapping Profile Configuration

Mapping profile configuration can be displayed using the command:

```
show qos-profile (type (cos-to-queue | dscp-to-queue | exp-to-queue | queue-color-to-cos | dscp-to-dscp | dscp-to-exp) |) (PROFILE-NAME|)
```

Refer to the "*Configuration Guide*" for detailed information of the mapping profile output.

Display Class-map Configuration

Class-map configuration can be verified with the command `show class-map (type qos|NAME|)`.

Sample output for the class-map configuration is shown below:

```
#show class-map type qos

 Type qos class-maps
 ===================
      class-map c1
         match vlan 200

      class-map type qos match-any class-default
```

Display policy-map configuration

Policy-map configuration can be verified with the command `show policy-map type qos (NAME|)`.

Sample output for the policy-map configuration is shown below:

```
#show policy-map type qos

Type qos policy-maps
====================

policy-map p1
 class c1
  police cir 2 mbps
  exit
```

Display Policy-map Configured on an Interface

Type qos policy-map configured on an interface is displayed by the command show policy-map interface INTERFACE-NAME type qos.

Sample output of this command is shown below:

```
#show policy-map interface xe1 type qos

Interface xe1
Type QoS statistics status : disabled

Service-policy (qos) input: parentPmap
---------------------------
Class-map (qos): vlan2 (match all)
 match vlan 2
 police cir 2 mbps

     Child Service-policy (qos) : childPmap
     ---------------------------
     Class-map (qos): class-default (match any)

     Class-map (qos): cos1 (match all)
      match cos 1
      police cir 1 mbps
```

To display a specific class within type qos policy-map configured on the interface use the command `show policy-map interface INTERFACE-NAME (class NAME|) type qos`.

Sample output of this command is shown below:

```
#show policy-map interface xe0 class cos1 type qos

Interface xe0

Type QoS statistics status : disabled

Class-map (qos): vlan2 (match all)
     Class-map (qos): cos1 (match all)
      match cos 1
      police cir 1 mbps
```

Displaying QoS packet and Byte Counters

QoS statistics can be enabled, displayed and cleared as described in following section:

- Enabling QoS packet and byte counters
- Displaying QoS packet and byte counters
- Clearing QoS packet and byte counters

Enabling QoS Packet and Byte Counters

Enable ingress and egress statistics using the command qos statistics as shown below.

```
(config)#qos statistics
```

The default for this command is disabled statistics.

Using no option statistics can be disabled.

Displaying QoS Packet and Byte Counters

Once statistics are enabled, type qos policy-map statistics and configurations can be displayed using the command `show policy-map interface INTERFACE-NAME type qos`.

A Sample output of this command is shown below:

```
#show policy-map interface xe0 type qos

Interface xe0

Type QoS statistics status : enabled

Class-map (qos): vlan2 (match all)
 match vlan 2
 police cir 2 mbps

     Class-map (qos): class-default (match any)
           matched      : 5503 packets, 8254500 bytes
           transmitted  : 92 packets, 138000 bytes
           dropped      : 5411 packets, 8116500 bytes

     Class-map (qos): cos1 (match all)
      match cos 1
      police cir 1 mbps
           matched      : 11010 packets, 16513500 bytes
           transmitted  : 94 packets, 141000 bytes
           dropped      : 10916 packets, 16372500 bytes
```

Statistics of type qos class-maps in the type qos policy-maps that are configured on the interfaces can be displayed using `show policy-map statistics (interface INTERFACE-NAME|) (class NAME|) type qos.`

A Sample output of this command is shown below:

```
#show policy-map statistics type qos
+---------------+----------------+----------------+----------------+-------------+
|    Class-map   |    Match pkts   |   Match bytes   |   Dropped pkts  |   Dropped Bytes
|
+---------------+----------------+----------------+----------------+-------------+
xe0
 vlan2
   cos1             9012              13516500          8935              13401000
xe2
 vlan2
   class-default    4452              6678000           4302              6453000

#show policy-map interface xe0 statistics type qos
+---------------+----------------+----------------+----------------+------------+
```

```
|    Class-map   |    Match pkts   |   Match bytes   |   Dropped pkts  |   Dropped Bytes
|
+----------------+-----------------+-----------------+-----------------+------------+
 vlan2
   cos1             1073131           1609695000        1063993           1595988000

#show policy-map statistics class cos1 type qos
+----------------+-----------------+-----------------+-----------------+-----------+
|    Class-map   |    Match pkts   |   Match bytes   |   Dropped pkts  |   Dropped Bytes
|
+----------------+-----------------+-----------------+-----------------+-----------+
xe0
 vlan2
   cos1             1399290           2098933500        1387374           2081059500

#show policy-map int xe0 statistics class cos1 type qos
+----------------+-----------------+-----------------+-----------------+----------+
|    Class-map   |    Match pkts   |   Match bytes   |   Dropped pkts  |   Dropped Bytes
|
+----------------+-----------------+-----------------+-----------------+----------+
 vlan2
   cos1             1563686           2345527500        1550370           2325553500
```

Note: In order to check statistics, QoS statistics profile need to be enabled for Qumran devices. QoS can either use ingress-acl statistics profile or ingress-qos statistics profile. When ACL groups are configured on the same interface as QoS and both ACL and QoS need explicit counters, then ingress-qos statistics profile need to be configured along with ingress-acl statistics profile. However, this will have other limitations on statistics profiles. Please refer hardware-profile statistics for more details.

Clearing QoS Packet and Byte Counters

QoS statistics can be cleared using the command `clear qos statistics`. This clears both ingress QoS and egress queuing statistics.

CHAPTER 12 Configuring Egress Queues on Ports

Every physical port of a Qumran device has eight priority queues and every subinterface has four priority queues. These ports and subinterfaces can be applied with several egress QoS parameters – these will be discussed in the next sections. (For more about subinterfaces, see Chapter 21, *Subinterface Queuing*.) When the QoS feature is enabled, all priority queues of the ports are configured with certain default egress queuing parameters.

To customize the treatment on the priority queues, the queuing policy-map infrastructure needs to be used. The following section explains the basic configuration details involved to apply queue level treatment on a port.

Configuring the Default Queuing Policy-Map

When the QoS feature is enabled, all ports of the Qumran device is supplied with a default policy-map of queuing type. The default policy-map is created with the name "`default-out-policy`" which is reserved and modifying parameters in this policy-map is reflected on all ports that do not have customized queuing policy-maps. Customized queuing policy-maps can be created and bound to ports to treat ports differently from the default configuration.

The `default-out-policy` policy-map is created with the default eight classes and the default subinterface `subif-default-out-policy` policy-map as Qumran supports eight priority queues per port and four priority queues per subinterface. Once the policy-map is configured, priority queue class-maps can be configured with the following command:

```
class type queuing default (q0|q1|q2|q3|q4|q5|q6|q7)
```

Class-maps qx represent the respective priority queuing class-maps which can be configured with different queue level parameters.

Creating a Queuing Class-Map

```
(no|) class-map type queuing NAME
```

Matching criteria: Only match queue is supported in queuing class-map for user-defined queuing policy-map.

```
(no|) match queue <0-7>
```

Note: The match queue range 0-7 is valid only for port queues classification.

For subinterface queues, the valid range is 0-3.

Creating a Queuing Policy-Map

The following is the command to create a customized default policy-map:

```
(no|) policy-map type queuing NAME
```

Binding a Queuing Policy-map

Customized queuing policy-maps take affect only when the configuration is bound to a port. Queuing policy-maps can be bound to the port with the following command:

```
service-policy type queuing output NAME
```

Where NAME represents the name of the queuing policy-map.

CHAPTER 13 Congestion Avoidance

Congestion avoidance techniques monitor network traffic loads in an effort to anticipate and avoid congestion at common network bottlenecks. Congestion avoidance is achieved through packet dropping. Among the more commonly used congestion avoidance mechanisms, Weighted Random Early Detection (WRED) is optimum for high-speed transit networks.

Qumran supports two types of congestion avoidance mechanisms.

- Tail drop – this is the default congestion avoidance behaviour when WRED is not configured
- WRED (Weighted Random Early Detection): This is applied only when configured

Tail Drop

Tail drop treats all traffic equally and does not differentiate between classes of service. Queues get filled during period of congestion. When the output queue is full and tail drop is in effect, packets are dropped until the congestion is eliminated and the queue is no longer full.

Configuring Packet Drop Priority Using Tail Drop

Qumran supports configuring color independent tail drop per queue, where the default queue-limit is 62914560 bytes (~62MB). The maximum queue limit (629145600) is not guaranteed in case of congestion because this is shared memory.

```
queue-limit <1-629145600> (packets | bytes | kbytes | mbytes | ms | us)
```

no queue-limit

Tail drop configurable parameters are listed below:

- Threshold in bytes, kilobytes, megabytes, packets or millisecond format.
- Ranges of different units are as follow:
    - Packets: min 9 – max 614400
    - Bytes: min 9416 – max 629145600
    - Kilo-bytes: min 9 – max 614400
    - Mega-bytes: max 600
    - Milliseconds: max 50
    - Microseconds: max50000

An example of configuring per-priority queue Tail Drop is shown below:

```
(config)#policy-map type queuing default pq-taildrop
(config-pmap-que-def)#class type queuing default q3
(config-pmap-c-que-def)#queue-limit 1 mbytes
(config-pmap-c-que-def)#exit
```

Queue Drop Counters Verification

Drop counters with drop reason can be verified globally by using the following command:

```
#show hardware-discard-counters
+----------------------------------------+---------------+--------------+
| Registers                              | Core 0        | Core 1       |
+----------------------------------------+---------------+--------------+
IQM_QUEUE_ENQ_DISCARDED_PACKET_COUNTER       1596100
   Reason: VOQ_VOQ_MX_QSZ_STATUS              Y
EGQ_PQP_DISCARD_UNICAST_PACKET_COUNTER       59807
   Reason: SRC_EQUAL_DEST_INT                 Y
```

Weighted Random Early Discard (WRED)

Qumran assigns each port eight priority queues to buffer traffic level that exceeds the port's total bandwidth. When traffic congestion persists, packets are dropped randomly. As a result traffic of greater priority may be dropped instead of traffic with lower priority.

In order to protect higher priority traffic from being dropped in such a scenarios, Qumran supports monitoring traffic congestion and drop packets based on a Weighted Random Early Discard (WRED) algorithm. Early detection of traffic congestion helps in avoiding global synchronization.

This algorithm enables the system to calculate current average queue length and compares the value against the configured minimum and maximum threshold values. Configured weight is a factor of calculating average queue length. If the calculated average queue length is within the configured minimum threshold, then the packet is enqueued. If the queue length is more than the configured maximum threshold, the packet will be dropped. When the queue length increases above minimum threshold and is within the configured maximum threshold, decision to enqueue or drop the packet is taken based on the configured drop probability. Higher drop probability packets are dropped and lower drop probability packets are enqueued.

When the current average queue length is slightly above the minimum threshold, packet drop count will be lower and increases as the current queue length reaches towards maximum threshold. Drop probability configuration decides the fraction of packet drops when average queue length reaches maximum threshold.

This method allows the application to take protective measures and synchronize the lost sessions over a period of time and thus avoiding sudden surges of traffic. Configurable parameters should be effective enough to provide enough time for the application to take corrective measures. If the gap between minimum threshold and maximum threshold values is small, then the time required for average queue length to increase from minimum threshold to maximum threshold is less and the algorithm will be ineffective.

Figure 13-119 shows how weighted random early discard works.

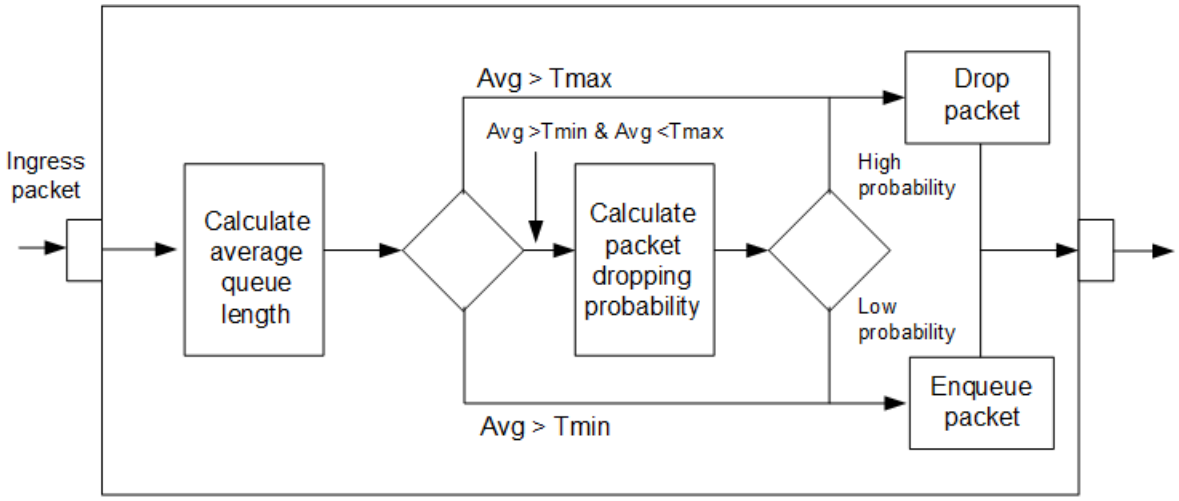

Figure 13-119: Weighted random early discard flow algorithm

Configuring Packet Drop Probability Using WRED

Qumran device supports both color independent per-priority queue WRED configuration and per-color, per-priority queue WRED configuration. One of the options is configurable per queue based on the requirement.

WRED configurable parameters are listed below:

- min_threshold: Minimal average queue size to apply WRED. Can be configured in bytes, kilobytes, megabytes, packets or millisecond format.
- max_thershold: Maximum average queue size to apply WRED. Can be configured in bytes, kilobytes, megabytes, packets or millisecond format.
- weight–factor of current size versus average size, in the calculation of new average size. Can be configured in range of 1 to 31 (optional).
- drop probability–maximum WRED drop probability applied at maximum threshold. Can be configured in percentage (optional).

At lower weight, average queue size will increase at the rate of instantaneous queue size, hence more packets will be dropped by WRED before queuing.

In this case, yellow packets are dropped more than green packets. At higher weight, average queue size will increase very slowly in comparison to instantaneous queue size, hence fewer packets will be dropped by WRED and more number packets will be queued. As a result we will observe similar results to tail drop.

Note: Formula to calculate new queue size:

NEW_AVG = OLD_AVG + (NEW_AVG-OLD_AVG) / (2 ^gain)

Formula to calculate drop probability:

Drop Probability = (AVRG_Q_SIZE-PQAVRGMINTH)/(PQAVRGMAXTH-PQAVRGMINTH) * 100%

It is recommended to use a weight value between 1 to 3 to achieve proper WRED functionality.

An example of configuring per-priority queue WRED is shown below:

```
(config)#policy-map type queuing default pq-wred
(config-pmap-que-def)#class type queuing default q3
(config-pmap-c-que-def)#random-detect 30 mbytes 500 mbytes drop-probability 50
(config-pmap-c-que-def)#exit
```

Both the minimum and maximum threshold must be configured in the same format. Thresholds can be configured in the range of 1 kilobyte to 600 megabytes or 50 milliseconds for millisecond format. In the above configuration, priority

queue q3 is configured with a minimum threshold of 30 megabytes and a maximum threshold of 500 megabytes and a drop probability of 50%.

```
random-detect (green|yellow|red|)(min-threshold|)<1-629145600>
(packets|bytes|bytes|mbytes|ms|us) (max-threshold|)<1-629145600>
(packets|bytes|kbytes|mbytes|ms|us)(drop-probability <1-100>|)
```

An example of configuring per-color, per-priority queue WRED is shown below:

```
(config)#policy-map type queuing default pq-c-wred
(config-pmap-que-def)#class type queuing default q3
(config-pmap-c-que-def)#random-detect yellow 30 mbytes 100 mbytes drop-probability 10
(config-pmap-c-que-def)#random-detect green 100 mbytes 300 mbytes drop-probability 10
(config-pmap-c-que-def)#random-detect weight 3
(config-pmap-c-que-def)#exit
```

Configuration allows minimum threshold, maximum threshold and drop probability to be configured differently for green packets and yellow packets. In the above configuration priority queue q3 will be configured with minimum threshold of 30 megabytes and maximum threshold of 100 megabytes for yellow with drop probability for 10% and minimum threshold of 100 mbps and max threshold of 300 mbps for green with drop probability of 10% for all colors along with a weight value of 3.

Follow “Chapter 12, *Configuring Egress Queues on Ports*” for complete configuration details of queuing property configuration.

Queue drop counters verification

Drop counters with drop reason can be verified globally by using the following command:

```
#show hardware-discard-counters
+-----------------------------------------+-------------+-------------+
| Registers                               | Core 0      | Core 1      |
+-----------------------------------------+-------------+-------------+
IQM_QUEUE_ENQ_DISCARDED_PACKET_COUNTER      1596100
   Reason: VOQ_WRED_STATUS                   Y
EGQ_PQP_DISCARD_UNICAST_PACKET_COUNTER      59807
   Reason: SRC_EQUAL_DEST_INT                Y
```

CHAPTER 14 Scheduling

Qumran can process all traffic if it is within the capacity of the device and all traffic will be forwarded as received. When the device reaches bandwidth constraint stage, traffic becomes subject to drop as described in "Configuring Packet Drop Probability Using WRED" or traffic scheduling as described in this section. Qumran classifies packets into one of eight internal priorities. Traffic scheduling allows to selectively forward traffic according to the forwarding queue that is mapped according to one of the following algorithm:

- Strict priority-based scheduling – This scheduling ensures the higher priority traffic is serviced ahead of lower priority traffic. As a result lower priority traffic may suffer from any access.
- WFQ (Weighted Fair Queuing) weight-based scheduling – In this scheduling, some weight based bandwidth is allocated to all queues. In this scheduling, egress traffic will be served based on the configured weight distribution.
- Mixed strict and weight based scheduling – This scheduling provides a mixture of strict priority for the higher priority queues and WFQ for the remaining priority queues. In this scheduling, strict priority should always be configured from highest to lower priority queues in sequential order and WFQ scheduling should be configured from lowest priority queues to higher priority queues in sequential order.

Configuring traffic scheduling

Traffic scheduling can be configured on a per port basis. It affects the outgoing traffic when bandwidth constraints occur. In Qumran device, all the eight queues of ports will be configured with strict priority scheduling by default when QoS feature is enabled. Strict priority level will correspond to the queue number.

Scheduling algorithms are configurable per priority queues using queuing policy-map infrastructure. The following section describes how to configure different types of scheduling:

- Configuring strict priority based traffic scheduling
- Calculating the values for WFQ Weight based traffic scheduling
- Configuring WFQ weight based traffic scheduling
- Configuring mixed strict priority and weight based scheduling

Configuring Strict Priority Based Traffic Scheduling

Qumran supports strict priority algorithm with 8 levels from 0 to 7. When QoS feature is enabled, all 8 default queues will be initialized with strict priority scheduling with level corresponding to queue number. Strict priority scheduling is configurable using the priority command on the default queuing class-maps in a queuing policy-map. Configuration takes effect when the queuing policy-map is bound to the egress interface. By default, all interfaces are configured with "default-out-policy" when QoS feature is enabled.

Below, is the command to configure strict priority based scheduling:

```
priority level <0-7>
```

An example of configuring "strict priority" is shown below:

```
(config)#policy-map type queuing default pq7-strict
(config-pmap-que-def)#class type queuing default q7
(config-pmap-c-que-def)#priority level 6
(config-pmap-c-que-def)#exit
```

Queues set with higher priority value will have higher priority. If more than one queue is set with strict priority scheduling with same level value, then there will be fair queuing between those queues

Default scheduling algorithm in Qumran device is WFQ weight based traffic scheduling with weight 1. Therefore, when strict priority configuration is removed, scheduling algorithm on that queue will be reset to WFQ with default weight 1.

Calculating the Values for WFQ Weight Based Traffic Scheduling

Weighted Fair Queueing (WFQ) scheduling weight is calculated as a percentage of the port's total bandwidth using the formula:

$$\text{Weight percentage of Q(x)} = \frac{WQ(x)}{WQ0 + WQ1 + WQ2 + WQ3 + WQ4 + WQ5 + WQ6 + WQ7}$$

```
Bandwidth percentage of Q(x) = Total bandwidth of port * weight percentage of Q(x)
```

Where:

WQ(x) is the value of the priority queue for which weight is to be determined.

WQ0-WQ7 is the assigned weight values of the eight queues – for example, if the weight values q0 to q7 are assigned as 3, 10, 5, 7, 18, 4, 9 and 1, then the Weight value of q4 can be calculated using the formula:

$$\text{Weight percentage of q4} = \frac{18}{3 + 10 + 5 + 7 + 18 + 4 + 9 + 1}$$

The weight of q4 is 31.6%. Q4 will get 31.6% of the port's total bandwidth.

Note: Due to a difference in hardware rate set values, a deviation of (<4%) is expected.

The example below explains how to derive weights based on bandwidth requirement on queues.

If the bandwidth requirement of Q0 is 5%, Q1 is 10%, Q2 is 10%, Q3 is 15% and remaining bandwidth for Q4, Q5, Q6 and Q7, then the weight for individual queue can be computed as:

Q0: 5, Q1: 10, Q2: 10, Q3: 15, Q4-Q7: (100 - 5 - 10 - 10 - 15) = 60

Equally dividing weight 60 among 4 queues will result in a weight of 15 per queue. So, the weights will be:

Q0: 5, Q1: 10, Q2: 10, Q3: 15, Q4: 15, Q5: 15, Q6: 15, Q7: 15

In this case, weight values can be simplified by dividing them with common denominator 5. So, the final set of weight values for q0 to q7 will be derived to be 1, 2, 3, 3, 3, 3, 3 and 3.

Configuring WFQ Weight Based Traffic Scheduling

Set the WFQ weight based scheduling with the following configuration:

```
(config)#policy-map type queuing default pq0-3-wfq
(config-pmap-que-def)#class type queuing default q0
(config-pmap-c-que-def)# wfq-queue weight 16
(config-pmap-c-que-def)#exit
```

where:

```
wfq-queue weight <1-127>
```

Weight values can be configured in the range of 1 to 127.

Configuring Mixed Strict Priority and Weight Based Traffic Scheduling

Qumran device supports mixed scheduling option where strict priority with same or different level values can be configured on few queues along with WFQ algorithm with same or different weights configured on other default queues. Queues configured with strict priority scheduling will have a higher weight over the queues with WFQ scheduling.

An example configuration is shown below:

```
(config)#policy-map type queuing default pq-mixed
```

```
(config-pmap-que-def)#class type queuing default q0
(config-pmap-c-que-def)# wfq-queue weight 4
(config-pmap-c-que-def)#exit
(config-pmap-que-def)#class type queuing default q1
(config-pmap-c-que-def)#priority level 3
(config-pmap-c-que-def)#exit
(config-pmap-que-def)#class type queuing default q2
(config-pmap-c-que-def)# wfq-queue weight 10
(config-pmap-c-que-def)#exit
(config-pmap-que-def)#class type queuing default q3
(config-pmap-c-que-def)#priority level 4
(config-pmap-c-que-def)#exit
(config-pmap-que-def)#class type queuing default q4
(config-pmap-c-que-def)# wfq-queue weight 30
(config-pmap-c-que-def)#exit
```

Classes 5 to 7 will be strict priority with corresponding level if these classes were not altered.

Follow “Chapter 12, *Configuring Egress Queues on Ports*” for complete configuration details of queuing property configuration.

Scheduling may be affected by resource exhaustion in case of multicast traffic.

Resource exhausted can be verified through drop reason as “RESOURCE_ERROR_STATUS.”

Queue drop counters verification

Drop counters with drop reasons can be verified globally using the command:

```
#show hardware-discard-counters
+---------------------------------+--------+--------+
| Registers                       | Core 0 | Core 1 |
+---------------------------------+--------+--------+
IQM_QUEUE_ENQ_DISCARDED_PACKET_COUNTER        1596100
   Reason:  RESOURCE_ERROR_STATUS               Y
            VOQ_MX_QSZ_STATUS                   Y
EGQ_PQP_DISCARD_UNICAST_PACKET_COUNTER        59807
      Reason: SRC_EQUAL_DEST_INT                Y
```

CHAPTER 15 Egress Port and Priority Rate Shaping

Rate shaping is a method of regulating traffic rate to ensure a certain level of network performance. The difference between policing and rate shaping is that policing drops the excess traffic. Shaping buffers the excess traffic and thus insures a uniform pattern of traffic egressing. Shaping is required when the nature of traffic is busty and needs to be smoothened.

Qumran supports configuring rate shaping per priority queue or per port.

Configuring port-based rate shaping

With Port based rate shaping, total traffic can be limited to the shape rate within the limits of port bandwidth. Qumran supports per-port rate shaping configuration within a range of 52kbps to 1000gbps. The shape rate granularity of the port shaper is 52kbps.

Note: Port based shaping is supported only on physical interfaces.

```
(config)#interface xe1
(config-if)#shape rate 200 mbps
(config-if)#exit
Syntax:
shape rate <1-1000000000> (kbps|mbps|gbps)
```

Configuring priority-based rate shaping

Priority based rate shaping ensures a traffic shaping per priority queue traffic. Priority based rate shaping is configured on the queuing class-map representing priority queue. Shaping can be configured in absolute value or in percentage of bandwidth. Qumran supports per-queue rate shaping configuration within a range of 469kbps to 483gbps. Granularity is 469 Kbps for low range and 1.56% for higher range.

The following example shows a sample configuration of priority based rate shaping:

```
(config)#policy-map type queuing default pq
(config-pmap-que-def)#class type queuing default q3
(config-pmap-c-que-def)#shape 10 mbps
(config-pmap-c-que-def)#exit
```

The general syntax is::

```
shape <1-483000000> (kbps|mbps|gbps) | percent <1-100>)
```

Follow “Chapter 12, *Configuring Egress Queues on Ports*.” for complete configuration details of queuing property configuration.

Queue drop counters verification

Drop counters with drop reasons can be verified globally by using the command:

```
#show hardware-discard-counters
+---------------------------------+--------+--------+
| Registers                       | Core 0 | Core 1 |
+---------------------------------+--------+--------+
IQM_QUEUE_ENQ_DISCARDED_PACKET_COUNTER        1596100
   Reason: VOQ_MX_QSZ_STATUS                   Y
EGQ_PQP_DISCARD_UNICAST_PACKET_COUNTER        59807
```

```
      Reason: SRC_EQUAL_DEST_INT                  Y
```

CHAPTER 16 Display Queuing Information

The following queuing information can be displayed:

- Queuing Configuration Information
- Queuing Packet and Byte Statistics

Displaying queuing configuration information

The queuing configurations that can be displayed are:

- Policy-map configuration
- Interface level queuing configuration

Display Policy-map Configuration

Use the following command to verify configurations on policy-map:

```
show policy-map (type queuing|NAME|)
```

NAME is an optional parameter which allows verifying a particular policy-map. Qumran supports only default queuing policy-maps.

Sample output for queuing policy-map configuration is shown below:

```
#show policy-map pq1

Type queuing policy-maps
========================

policy-map type queuing default pq1
 class type queuing default q0
  shape percent 60
  wfq-queue weight 20
  exit
 class type queuing default q1
  shape percent 20
  wfq-queue weight 50
  exit
 class type queuing default q2
  priority level 2
  exit
 class type queuing default q3
  priority level 3
  exit
 class type queuing default q4
  priority level 4
  exit
 class type queuing default q5
  priority level 5
  exit
 class type queuing default q6
  priority level 6
```

```
  exit
 class type queuing default q7
  priority level 7
  exit
```

Interface level queuing configuration

The following command shows the configuration on eight priority queues of an interface:

```
show queuing interface INTERFACE-NAME
```

Sample output of interface based queue configuration is shown below:

```
#show queuing interface xe1

Egress Queuing for Ethernet xe1 [System]
------------------------------------------------------
L0   L1   L2   Group   PrioLevel  Shape      Bandwidth
------------------------------------------------------
q0             -       -          60 percent     -
q1             -       -          20 percent     -
q2             -       High       -              -
q3             -       High       -              -
q4             -       High       -              -
q5             -       High       -              -
q6             -       High       -              -
q7             -       High       -              -
```

Display Type Queuing Policy-map Configuration and Statistics on an Interface

Type queuing policy-map configurations and statistics can be displayed using the command:

```
show policy-map interface INTERFACE-NAME type queuing
```

Sample output is shown below:

```
#show policy-map interface xe0 type queuing

Interface xe0
Type Queuing policy-map : pq1

Class-map (queuing): class-default-q
 shape 1000000 kbps (inherited)
 wfq-queue weight 1
 queue-limit 1253376 bytes/10 ms (default)
 match queue 0
      Output
         Total        : 14303226 packets, 21454839000 bytes
         Green        : 14303226 packets, 21454839000 bytes
         Yellow       : 0 packets, 0 bytes
 match queue 1
 match queue 2
 match queue 3
 match queue 4
```

```
 match queue 5
 match queue 6
 match queue 7

Class-map (queuing): service3
 match service-template v3
 shape 1000000 kbps (inherited)
 wfq-queue weight 1

     Class-map (queuing): class-default-q
      shape 1000000 kbps (inherited)
      wfq-queue weight 1

     Class-map (queuing): data
      shape 1000000 kbps (inherited)
      wfq-queue weight 1
      queue-limit 1253376 bytes/10 ms (default)
      match queue 0
      match queue 1
           Output
              Total        : 4717105 packets, 7075660500 bytes
              Green        : 4717122 packets, 7075684500 bytes
              Yellow       : 0 packets, 0 bytes
           Rate            : 118443.625 kbps
      match queue 2
```

Configurations and statistics of a particular class in the type queuing policy-map on an interface can be displayed using the command `show policy-map interface INTERFACE-NAME (class NAME|) type queuing`

Sample output is shown below:

```
#show policy-map interface xe2 class service3

Interface xe2
Type Queuing policy-map : pq1

Class-map (queuing): service3
 match service-template v3
 shape 1000000 kbps (inherited)
 wfq-queue weight 1

     Class-map (queuing): class-default-q
      shape 1000000 kbps (inherited)
      wfq-queue weight 1
      queue-limit 1253376 bytes/10 ms (default)
      match queue 2
           Output
              Total        : 111200 packets, 166801500 bytes
              Green        : 111209 packets, 166813500 bytes
              Yellow       : 0 packets, 0 bytes
```

```
      Rate            : 59141.176 kbps
 match queue 3

Class-map (queuing): data
 shape 1000000 kbps (inherited)
 wfq-queue weight 1
 queue-limit 1253376 bytes/10 ms (default)
 match queue 0
 match queue 1
      Output
         Total        : 222450 packets, 333678000 bytes
         Green        : 222466 packets, 333702000 bytes
         Yellow       : 0 packets, 0 bytes
      Rate            : 118287.391 kbps
```

CHAPTER 17 Display Queue Level Packet and Byte Counters

Queue level statistics can be displayed and cleared as described in the following section:

- Displaying queuing class configuration and queue packet and byte counters
- Clearing queue level packet and byte counters

Queue level statistics can be displayed using the command:

`show policy-map (interface INTERFACE-NAME|) statistics (class CLASS-NAME|) type queuing` and

`show interface (INTERFACE-NAME|) counters queue-stats`.

Sample output is shown below:

```
#show policy-map statistics type queuing
+----------------+----------------+----------------+----------------+--------------+

```

Display Queue Level Instantaneous Transmission Rate

The instantaneous rate at which packets are de queued/transmitted from the queues can be displayed using

`show policy-map (interface INTERFACE-NAME|) statistics (class CLASS-NAME|) type queuing (rate (kbps|mbps|gbps)|)`

Sample output of the command is shown below:

```
#show policy-map statistics type queuing rate mbps
+------------------------+----------------+
|            Class-map   | Rate (in mbps) |
+------------------------+----------------+
xe0
 q1                              1.031
 q3                              1.031
xe2
 q1                              1.031
 q2                              0.824

#show policy-map interface xe0 statistics type queuing rate mbps
+------------------------+---------------+
|            Class-map   | Rate (in mbps)|
+------------------------+---------------+
 q1                              0.700
 q3                              1.168

#show policy-map interface xe0 statistics class q1 type queuing rate mbps
+-----------------------+----------------+
|            Class-map  | Rate (in mbps) |
+-----------------------+----------------+
 q1                              0.937
```

Clearing Queue Level Packet and Byte Counters

Queue statistics can be cleared using the command:

```
clear qos statistics (interface INTERFACE-NAME |) output type queuing
```

and

```
clear interface counters.
```

CHAPTER 18 VLAN Service Queuing (VLAN Shaping)

In Qumran device, every port has default eight priority queues that can be applied. Whenever QoS feature is enabled, all priority queues of the ports will be configured with certain default egress queuing parameters. In order to customize the treatment on the priority queues, queuing policy-map infrastructure need to be used.

Service Queuing refers to mapping services to specific vlans and shaping each vlan based traffic. Within the vlan, queues can be grouped and shaped independently.

Configuring VLAN Shaping

The following section explains the configuration of basic infrastructure to provide the functionality of queuing per services on an interface. These queues will support all the possible QoS treatment via egress queuing policy-map configurations. Services can be mapped using service-template or via match vlan. Whenever we will be matching a service in a class inside a policy and attach it on interface, 4 new queues will be created for these services. User can create max 3-level scheduling hierarchy for each of the services using these policy-maps.

Policy-map attached to interface will be referred as "L0" level policy-map. Each child policy-map that will be added, will be at one incremented level i.e. L0-level's child policy-map will be L1 level policy-map and L1-level's child will be L2 policy-map. This is the max 3-level hierarchy supported in user defined policy-map.

Class-default-q is a self-created class map as part a policy map. There are two types of class-default-q CMAPs:

- When a policy is applied on an interface, the class-default-q represents the port default queues. If the operator wants to shape or apply certain TailDrop/WRED properties on the port queues, it has to be applied on the class-default-q cmap at Level 0.
- When a child policy is attached to a cmap with some service match criteria (match service-template/vlan), the class-default-q cmap in the child policy represents the queues which are left unmatched in rest of the cmaps of the child policy.

Configuring a Queuing Policy-map

When QoS feature is enabled, all ports in the Qumran device will be applied with a default policy-map of queuing type. The default policy-map is created with the name “default-out-policy” which is reserved and modifying parameters in this policy-map will reflect on all ports which don't have customized queuing policy-map. Customized queuing policy-maps can be created and bound to ports to treat ports differently from default configuration.

Creating a user-defined queuing policy-map

Qumran device supports creation of customized policy-map in which new four queues can be configured for each services. If any priority queue class-map is not configured, default behavior among these new queues is weighted fair queuing. New queues and port default queues will also have weighted fair queuing between them as default behavior.

The following command is used to create a class-map:

```
(no|) class-map type queuing NAME
```

These class-maps will be matching some services for which new queues will be created. These classes can be empty classes in order to create hierarchy and club services in a hierarchy.

Matching criteria of a queuing class-map

Queuing class-map can have four matching criteria:

1. queue: queue selection

   ```
   CLI:  (no|) match queue <0-7>
   ```

   Note: match queue range 0-7 is valid only for port queues classification.

   For service queues, valid range is 0-3.

2. service-template: service related classification

   ```
   CLI: (no|) match service-template NAME
   ```

3. vlan: list VLAN ID

   ```
   CLI:  (no|) match vlan <1-4094>
   ```

4. interface: interface name

   ```
   CLI: (no|) match interface IFNAME
   ```

   Note: The interface name can be either vlan interface or subinterface.

The following is the command to create a customized policy-map:

```
(no|) policy-map type queuing NAME
```

Once the policy-map is configured, the queuing class-maps can be configured with following command:

```
(no|) class type queuing NAME
```

Binding/Unbinding a QoS Policy-map on an Interface

Customized queuing policy-maps take affect only when the configuration is bound to a port.

Queuing policy-maps can be bound/unbound to the out-port with following command:

```
(no|) service-policy type queuing output NAME
```

Where “NAME” represents the name of the queuing policy-map.

Binding/Unbinding a QoS Policy-map as a Child Service Policy

A policy-map can be configured as a child policy in order to create a hierarchy. Queuing policy-maps can be bound to a policy-map as a child policy with following command:

```
(no|) service-policy NAME
```

Where NAME represents the name of the queuing policy-map.

Note: Child policy needs to be attached to a parent policy-map inside a class.

For example:

```
class-map type queuing data
 match queue 0
!
class-map type queuing service1
 match service-template ETH-2016
!
class-map type queuing service2
 match service-template ETH-2017
```

```
!
class-map type queuing signal
 match queue 3
!
class-map type queuing voice
 match queue 1
!
policy-map type queuing configPolicy1
 class type queuing class-default-q
  exit
 class type queuing data
  exit
 class type queuing signal
  exit
 class type queuing voice
  exit
!
policy-map type queuing customer1
 class type queuing service1
  service-policy configPolicy1
class type queuing class-default-q
  exit
!
interface xe11
 service-policy type queuing output customer1
```

Here, “customer1” is L0-level policy-map and “configPolicy1” is L1-level policy-map. Policy-map “customer1” is having a class-default-q which is having port default queues. Policy-map “configPolicy1” is having class-default-q which is representing remaining queue i.e. queue 2 as queue3 is mapped to class signal, queue1 is mapped to class voice and queue0 is mapped to class data.

WRED and taildrop configuration is applicable only in the class in which queues are mapped. If in a policy-map having a class matching the service is not having any child policy-map, then all the new queues will be mapped to the same class and WRED and taildrop configuration is valid for this class. If the class matching service is having child policy matching queues, then WRED and taildrop is valid for the child service-policy only.

Policy-map having classes matching the queues can only be configured as a child service-policy inside a class matching service or at L0 class-default-q. It cannot be attached on an interface directly

If the user-defined child service policy is applied matching queues in L0 class-default-q which are mapping port queues, supported match queue range is 0-7.

For service queues, valid range is 0-3 as only 4 new queues are created for each service.Since the queues created are 4, 8 traffic classes are mapped implicitly to 4 queues as shown in Table 18-81.

Table 18-81: Traffic class to queue mapping

Traffic class	Queue
0	0
1, 2, 3	1
4, 5	2
6, 7	3

Ingress mapping profile like cos-to-queue, dscp-to-queue, and exp-to-queue actually maps packet fields (cos/dscp/exp) to 8 traffic classes. These traffic classes are mapped one-to-one when we have 8 queues in case of physical port and to 4 queues in case of services as shown above.

Until the child service-policy is applied on L0 class-default-q (port queues), port queues will follow default mapping profiles.

QoS feature must be enabled to configure policy-maps. This infrastructure contains two entities - class-map and policy-map. Class-map holds the match criteria and class-maps can be bound to policy-map to configure QoS treatment for the matching traffic.

The following section explains the basic configuration details involved to apply queue level treatment on the port.

Note: Please refer to *MPLS configuration guide* for service-template configurations.

```
(config)# class-map type queuing customer1
(config-cmap-que)# match service-template customer1Vlan
(config-cmap-que)#exit
(config)# class-map type queuing customer2
(config-cmap-que)# match service-template customer2Vlan
(config-cmap-que)#exit
(config)# class-map type queuing customer3
(config-cmap-que)# match service-template customer3Vlan
(config-cmap-que)#exit
(config)# class-map type queuing customer4
(config-cmap-que)# match service-template customer4Vlan
(config-cmap-que)#exit

(config)#class-map type queuing data
(config-cmap-que)# match queue 0

 match queue 3
```

```
 match queue 4
 match queue 5
 match queue 6
 match queue 7
```

QoS Configuration on User-defined Policy-map

All the queuing configurations such as WRED, taildrop, WFQ, shaping are same for user-defined policy as they are in default-policy-map except the priority queue configuration.

In default-policy-map, max priority supported is 8 i.e. 0-7, while in user-defined policy-map, max priority level is 4, i.e.0-3.

Priority class will always have priority over weighted class in default policy. But in user-defined policy, when all the 4 priorities are assigned with weighted classes, priority 0 class will be in fair queuing with the total weighted queues. If 3 or less than 3 priority class are present with weighted classes, than priority class will have priority over weighted class.

For example:

```
(config-pmap-que)#policy-map type queuing area2_policy
 (config-pmap-que)# class type queuing customer1
 (config-pmap-c-que)# priority level 0
 (config-pmap-c-que)# service-policy traffic_policy
 (config-pmap-que)# class type queuing customer2
 (config-pmap-c-que)# priority level 1
 (config-pmap-c-que)# service-policy traffic_policy
 (config-pmap-que)# class type queuing customer3
 (config-pmap-c-que)# priority level 2
 (config-pmap-c-que)# service-policy traffic_policy
 (config-pmap-que)# class type queuing customer4
 (config-pmap-c-que)# priority level 3
 (config-pmap-c-que)# service-policy traffic_policy
 (config-pmap-que)# class type queuing customer5
 (config-pmap-c-que)# wfq-queue weight 1
 (config-pmap-c-que)# service-policy traffic_policy
  (config-pmap-que)# class type queuing customer6
 (config-pmap-c-que)# wfq-queue weight 2
 (config-pmap-c-que)# service-policy traffic_policy
```

In this case, customer4 will have the highest priority, while 50% of the remaining bandwidth after distributing among priority classes will be used by Customer1, and the remaining 50% will be shared by Customer5 and Customer6 (FQ between priority 0 and weighted class).

If there are only three priority classes, for example:

```
(config-pmap-que)#policy-map type queuing area2_policy
(config-pmap-que)# class type queuing customer1
(config-pmap-c-que)# priority level 0
(config-pmap-c-que)# service-policy traffic_policy
(config-pmap-que)# class type queuing customer2
(config-pmap-c-que)# priority level 1
(config-pmap-c-que)# service-policy traffic_policy
(config-pmap-que)# class type queuing customer3
(config-pmap-c-que)# priority level 2
(config-pmap-c-que)# service-policy traffic_policy
```

```
(config-pmap-que)# class type queuing customer4
(config-pmap-c-que)# wfq-queue weight 1
(config-pmap-c-que)# service-policy traffic_policy
(config-pmap-que)# class type queuing customer5
(config-pmap-c-que)# wfq-queue weight 2
(config-pmap-c-que)# service-policy traffic_policy
```

Here, Customer3 has the highest priority. Customer1 has priority 0 and will have priority over Custimer4 and Customer5.

Configuration Considerations

- Max 3 level of user defined hierarchy is supported.
- Class-default-q is a self-created class map as part a policy map. It cannot be created nor be destroyed. It will be displayed (on whichever level applicable) only when user access it. Executing command "no class-default-q", will un-configure all the configurations of class-default-q.
- User can configure all queuing parameters like weight, priority, queue-limit, wred and shape in a class inside policy.
- Queue-limit and wred is only applicable in class matching queues.
- Same service should not be matched twice in the same hierarchy at any level.
- Policy-map with classes matching queues can only be attached to the policy-map having classes with match service or L0 class-default-q class.
- Child service policy is not allowed in class matching queues unless it is L0 class-default-q.
- If a service-policy is configured as a child policy in any hierarchy, then it cannot be attached on an interface directly and vice-versa.
- All the classes inside a policy-map should have same matching criteria but not same matching criteria value.
- Class-default-q class will only be present at L0 level or at the last level in a hierarchy. Class-default-q class will be matching port default queues if the class is of L0. Class-default-a class will be matching remaining queues in the newly created queue bundle if not matched in a class.
- Valid match queue range for classifying port-queues is 0-7. For service queue it is 0-3.
- Update is possible in the policy-map except the update of match criteria. Once the class with some match criteria is used in a policy-map, it cannot be updated.
- Max 4 priority queues are supported in non-default queuing policy-map.
- VLAN shaping is only supported for L2VPN, L3VPN, and provider-bridging services.

Service Queuing refers to mapping services to specific vlans and shaping each vlan based traffic. Within the vlan, queues can be grouped and shaped independently.

Matching of traffic can be based on different parameters such as service-template, VLAN, sub interface/VLAN interface.

Below, are different configuration for L2VPN, VPLS/VPWS services, L3VPN with sub and VLAN interfaces, and a provider bridge configuration.

L2VPN- VPLS

Figure 18-120 displays a six node topology configured with end to end connectivity from Router 1 to Router 6. The end to end connectivity is established by configuring OSPF, iBGP and LDP configuration in all the routers. We should be able to ping each device from other device from topology. Configure L2VPN- VPLS services on RTR1 and RTR6 and create Qos configuration on RTR6 and verify service queuing.

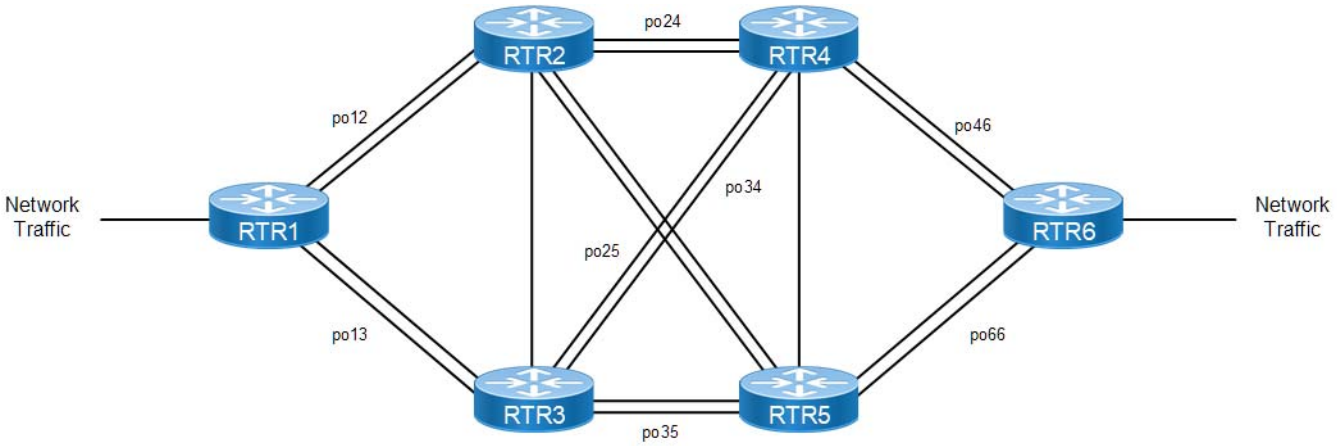

Figure 18-120: Simple Topology

RTR1

`RTR1#configure terminal`	Enter into configuration mode
`RTR1(config)#service-template VPLS-30`	Create L2VPN VPLS service template of VPLS-30
`RTR1(config-svc)# match double-tag outer-vlan 30 inner-vlan 2030`	Match for double tagged VLAN with inner VLAN 30 and outer VLAN 2030
`RTR1(config-svc)#rewrite ingress pop outgoing-tpid dot1.q`	Rewrite ingress pop outgoing as dot1q
`RTR1(config-svc)#exit`	Exit
`RTR1(config)#service-template VPLS-40`	Create L2VPN VPLS service template of VPLS-40
`RTR1(config-svc)#match double-tag outer-vlan 40 inner-vlan 2040`	Match for double tagged VLAN with inner VLAN 40 and outer VLAN 2040
`RTR1(config-svc)#rewrite ingress pop outgoing-tpid dot1.q`	Rewrite ingress pop outgoing as dot1q
`RTR1(config-svc)#exit`	Exit
`RTR1(config)#mpls vpls V30 30`	Create MPLS VPLS with V30 and 30
`RTR1(config-vpls)#service-tpid dot1.ad`	Make service tpid as dot1.ad
`RTR1(config-vpls)#signaling ldp`	Configure signaling as ldp
`RTR1(config-vpls-sig)#vpls-type vlan`	Configure vpls type as vlan
`RTR1(config-vpls-sig)#vpls-peer 6.6.6.6`	Configure peer as 6.6.6.6
`RTR1(config-vpls-sig)#exit-signaling`	Exit
`RTR1(config-vpls)#exit`	Exit
`RTR1(config)#mpls vpls V40 40`	Create MPLS VPLS with V40 and 40
`RTR1(config-vpls)#service-tpid dot1.ad`	Make service tpid as dot1.ad
`RTR1(config-vpls)#signaling ldp`	Configure signaling as LDP
`RTR1(config-vpls-sig)#vpls-type vlan`	Configure VPLS type as VLAN
`RTR1(config-vpls-sig)#vpls-peer 6.6.6.6`	Configure peer as 6.6.6.6
`RTR1(config-vpls-sig)#exit-signaling`	Exit
`RTR1(config-vpls)#exit`	Exit
`RTR1(config)#interface xe14`	Enter interface configuration

RTR1(config-if)#switchport	Change port as switchport
RTR1(config-if)#load-interval 30	Configure load interval as 30
RTR1(config-if)#mpls-vpls V30 service-template VPLS-30	Bind MPLS VPLS V30 with service template VPLS-30
RTR1(config_if_vpls)#ac-admin-status up	Change admin status as UP
RTR1(config_if_vpls)#exit-if-vpls	Exit
RTR1(config-if)#mpls-vpls V40 service-template VPLS-40	Bind MPLS VPLS V40 with service template VPLS-40
RTR1(config_if_vpls)#ac-admin-status up	Change admin status as UP
RTR1(config_if_vpls)#exit-if-vpls	Exit
RTR1(config)#router bgp 64512	Configure BGP of as number 64512
RTR1(config-router)#address-family l2vpn vpls	Enter into l2vpn VPLS address family
RTR1(config-router-af)#neighbor 6.6.6.6 activate	Activate neighbor 6.6.6.6
RTR1(config-router-af)#exit-address-family	Exit
RTR1(config-router)#exit	Exit

RTR6

RTR6#configure terminal	Enter into configuration mode
RTR6(config)#service-template VPLS-30	Create L2VPN VPLS service template of VPLS-30
RTR6(config-svc)#match double-tag outer-vlan 30 inner-vlan 2030	Match for double tagged VLAN with inner VLAN 30 and outer VLAN 2030
RTR6(config-svc)#rewrite ingress pop outgoing-tpid dot1.q	Rewrite ingress pop outgoing as dot1q
RTR6(config-svc)#exit	Exit
RTR6(config)#service-template VPLS-40	Create L2VPN VPLS service template of VPLS-40
RTR6(config-svc)#match double-tag outer-vlan 40 inner-vlan 2040	Match for double tagged VLAN with inner VLAN 40 and outer VLAN 2040
RTR6(config-svc)#rewrite ingress pop outgoing-tpid dot1.q	Rewrite ingress pop outgoing as dot1q
RTR6(config-svc)#exit	Exit
RTR6(config)#mpls vpls V30 30	Create MPLS VPLS with V30 and 30
RTR6(config-vpls)#service-tpid dot1.ad	Make service tpid as dot1.ad
RTR6(config-vpls)#signaling ldp	Configure signaling as LDP
RTR6(config-vpls-sig)#vpls-type vlan	Configure VPLS type as VLAN
RTR6(config-vpls-sig)#vpls-peer 1.1.1.1	Configure peer as 1.1.1.1
RTR6(config-vpls-sig)#exit-signaling	Exit
RTR6(config-vpls)#exit	Exit
RTR6(config)#mpls vpls V40 40	Create MPLS VPLS with V40 and 40
RTR6(config-vpls)#service-tpid dot1.ad	Make service tpid as dot1.ad
RTR6(config-vpls)#signaling ldp	Configure signaling as LDP
RTR6(config-vpls-sig)#vpls-type vlan	Configure VPLS type as VLAN

`RTR6(config-vpls-sig)#vpls-peer 1.1.1.1`	Configure peer as 1.1.1.1
`RTR6(config-vpls-sig)#exit-signaling`	Exit
`RTR6(config-vpls)#exit`	Exit
`RTR6(config)#interface xe13`	Enter interface configuration
`RTR6(config-if)#switchport`	Change port as switchport
`RTR6(config-if)#load-interval 30`	Configure load interval as 30
`RTR6(config-if)#mpls-vpls V30 service-template VPLS-30`	Bind MPLS VPLS V30 with service template VPLS-30
`RTR6(config_if_vpls)#ac-admin-status up`	Change admin status as UP
`RTR6(config_if_vpls)#exit-if-vpls`	Exit
`RTR6(config-if)#mpls-vpls V40 service-template VPLS-40`	Bind MPLS VPLS V40 with service template VPLS-40
`RTR6(config_if_vpls)#ac-admin-status up`	Change admin status as UP
`RTR6(config_if_vpls)#exit-if-vpls`	Exit
`RTR6(config)#router bgp 64512`	Configure BGP of as number 64512
`RTR6(config-router)#address-family l2vpn vpls`	Enter into l2vpn VPLS address family
`RTR6(config-router-af)#neighbor 1.1.1.1 activate`	Activate neighbor 1.1.1.1
`RTR6(config-router-af)#exit-address-family`	Exit
`RTR6(config-router)#exit`	Exit
`RTR6(config)#qos enable`	Enable QoS
`RTR6(config)#class-map type queuing que0`	Create class map of type queuing with name que0
`RTR6(config-cmap-que)# match queue 0`	Match for queue 0
`RTR6(config-cmap-que)#class-map type queuing que1`	Create class map of type queuing with name que1
`RTR6(config-cmap-que)#match queue 1`	Match for queue 1
`RTR6(config-cmap-que)#class-map type queuing que2`	Create class map of type queuing with name que2
`RTR6(config-cmap-que)#match queue 2`	Match for queue 2
`RTR6(config-cmap-que)#class-map type queuing que3`	Create class map of type queuing with name que3
`RTR6(config-cmap-que)#match queue 3`	Match for queue 3
`RTR6(config-cmap-que)#class-map type queuing service30`	Create class map of type queuing with name VPLS-30
`RTR6(config-cmap-que)#match service-template VPLS-30`	Match for service template VPLS-30
`RTR6(config-cmap-que)#class-map type queuing service40`	Create class map of type queuing with name VPLS-40
`RTR6(config-cmap-que)#match service-template VPLS-40`	Match for service template VPLS-40
`RTR6(config-cmap-que)#policy-map type queuing queue`	Create policy map with name queue
`RTR6(config-pmap-que)#class type queuing que0`	Add class map que0 to above policy map

RTR6(config-pmap-c-que)#exit	Exit
RTR6(config-pmap-que)#class type queuing que1	Add class map que1 to above policy map
RTR6(config-pmap-que)#shape 100 mbps	Shape traffic to 100 mbps
RTR6(config-pmap-c-que)#exit	Exit
RTR6(config-pmap-que)#class type queuing que2	Add class map que2 to above policy map
RTR6(config-pmap-que)#shape 100 mbps	Shape traffic to 100 mbps
RTR6(config-pmap-c-que)#exit	Exit
RTR6(config-pmap-que)#class type queuing que3	Add class map que3 to above policy map
RTR6(config-pmap-c-que)#exit	Exit
RTR6(config-pmap-que)#policy-map type queuing service	Create policy map with name service
RTR6(config-pmap-que)#class type queuing service30	Add class map service30 to above policy map
RTR6(config-pmap-que)#shape 1000 mbps	Shape rate to 1000 mbps
RTR6(config-pmap-c-que)#service-policy queue	Add policy map queue as service-policy
RTR6(config-pmap-c-que)#exit	Exit
RTR6(config-pmap-que)#class type queuing service40	Add class map service40 to above policymap
RTR6(config-pmap-c-que)#service-policy queue	Add policy map queue as service-policy
RTR6(config-pmap-c-que)#exit	Exit
RTR6(config-pmap-que)#interface xe13	Configure interface xe13
RTR6(config-if)#service-policy type queuing output service	Attach the policy map service to the interface
RTR6(config-if)#shape rate 3000 mbps	Shape rate traffic to 3000 mbps
RTR6(config-if)#exit	Exit

L2VPN- VPWS

Figure 18-121 displays a six node topology configured ith end to end connectivity from Router 1 to Router 6. The end to end connectivity is established by configuring OSPF, iBGP and LDP configuration in all the routers. We should be able to ping each device from other device from topology. Configure L2VPN- VPWS services on RTR1 and RTR6 and create Qos configuration on RTR6 and verify service queuing.

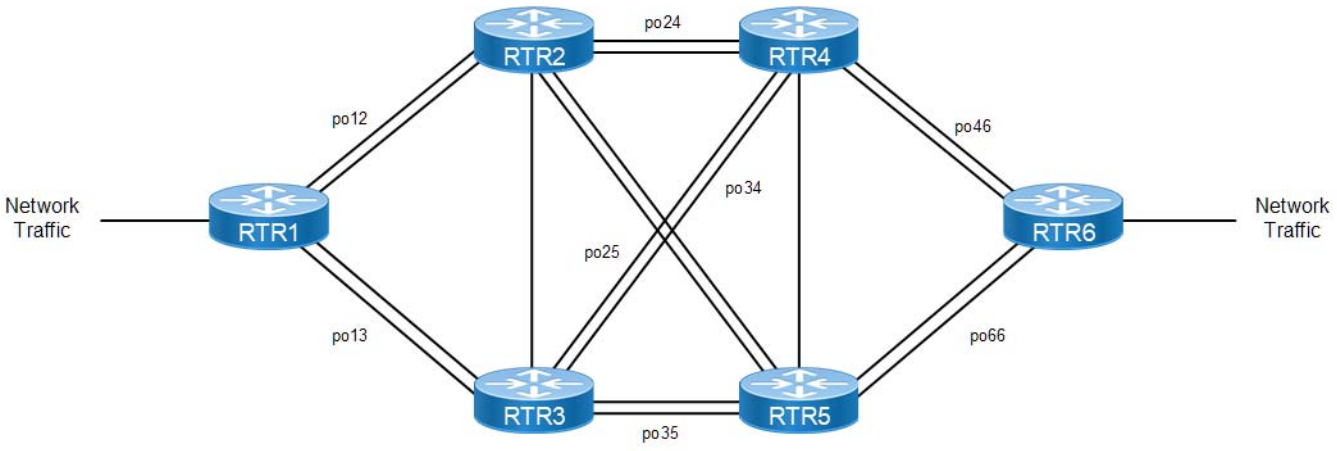

Figure 18-121: Simple Topology

RTR1

`RTR1#configure terminal`	Enter into configuration mode
`RTR1(config)#mpls l2-circuit VPWS10 10 6.6.6.6`	Create MPLS l2 circuit with VPWS10 with ID 10 and end point 6.6.6.6

`RTR1(config)#mpls l2-circuit VPWS20 20 6.6.6.6`	Create MPLS l2 circuit with VPWS20 with ID 20 and end point 6.6.6.6
`RTR1(config)#service-template VPWS-10`	Create service template VPWS-10
`RTR1(config-svc)#match outer-vlan 10`	Match outer vlan 10
`RTR1(config-svc)#rewrite ingress translate 1000 outgoing-tpid dot1.q`	Rewrite ingress translate 1010 with outgoing tpid as dot1q
`RTR1(config-svc)#exit`	Exit
`RTR1(config)#`	
`RTR1(config-svc)#service-template VPWS-20`	Create service template VPWS-20
`RTR1(config-svc)# match outer-vlan 20`	Match outer vlan 20
`RTR1(config-svc)# rewrite ingress translate 1020 outgoing-tpid dot1.q`	Rewrite ingress translate 1020 with outgoing tpid as dot1q
`RTR1(config-svc)#exit`	Exit
`RTR1(config)#interface xe14`	Configure interface xe14
`RTR1(config-if)#switchport`	Configure as layer 2 port
`RTR1(config-if)#load-interval 30`	Configure load interval as 30
`RTR1(config-if)#mpls-l2-circuit VPWS10 service-template VPWS-10`	Attach l2circuit VPWS10 with service template VPWS-10
`RTR1(config-if)#mpls-l2-circuit VPWS20 service-template VPWS-20`	Attach l2circuit VPWS20 with service template VPWS-20
`RTR1(config-if)#exit`	exit

RTR6

`RTR6#configure terminal`	Enter into configuration mode
`RTR6(config)#mpls l2-circuit VPWS10 10 1.1.1.1`	Create MPLS l2 circuit with VPWS10 with ID 10 and end point 1.1.1.1
`RTR6(config)#mpls l2-circuit VPWS20 20 1.1.1.1`	Create MPLS l2 circuit with VPWS20 with ID 20 and end point 1.1.1.1
`RTR6(config)#service-template VPWS-10`	Create service template VPWS-10
`RTR6(config-svc)# match outer-vlan 10`	Match outer vlan 10
`RTR6(config-svc)# rewrite ingress translate 1000 outgoing-tpid dot1.q`	Rewrite ingress translate 1010 with outgoing tpid as dot1q
`RTR6(config-svc)#exit`	Exit
`RTR6(config-svc)#service-template VPWS-20`	Create service template VPWS-20
`RTR6(config-svc)#match outer-vlan 20`	Match outer VLAN 20
`RTR6(config-svc)#rewrite ingress translate 1020 outgoing-tpid dot1.q`	Rewrite ingress translate 1020 with outgoing tpid as dot1q
`RTR6(config-svc)#exit`	Exit
`RTR6(config)#interface xe14`	Configure interface xe14
`RTR6(config-if)#switchport`	Configure as layer 2 port
`RTR6(config-if)#load-interval 30`	Configure load interval as 30
`RTR6(config-if)#mpls-l2-circuit VPWS10 service-template VPWS-10`	Attach l2circuit VPWS10 with service template VPWS-10

`RTR6(config-if)#mpls-l2-circuit VPWS20 service-template VPWS-20`	Attach l2circuit VPWS20 with service template VPWS-20
`RTR6(config-if)#exit`	exit
`RTR6(config)#qos enable`	Enable Qos
`RTR6(config)#class-map type queuing que0`	Create class map of type queuing with name que0
`RTR6(config-cmap-que)# match queue 0`	Match for queue 0
`RTR6(config-cmap-que)#class-map type queuing que1`	Create class map of type queuing with name que1
`RTR6(config-cmap-que)#match queue 1`	Match for queue 1
`RTR6(config-cmap-que)#class-map type queuing que2`	Create class map of type queuing with name que2
`RTR6(config-cmap-que)#match queue 2`	Match for queue 2
`RTR6(config-cmap-que)#class-map type queuing que3`	Create class map of type queuing with name que3
`RTR6(config-cmap-que)#match queue 3`	Match for queue 3
`RTR6(config-cmap-que)#class-map type queuing service10`	Create class map of type queuing with name VPWS-10
`RTR6(config-cmap-que)#match service-template VPWS-10`	Match for service template VPWS-10
`RTR6(config-cmap-que)#class-map type queuing service20`	Create class map of type queuing with name VPWS-20
`RTR6(config-cmap-que)#match service-template VPWS-20`	Match for service template VPWS-20
`RTR6(config-cmap-que)#policy-map type queuing queue`	Create policy map with name queue
`RTR6(config-pmap-que)#class type queuing que0`	Add class map que0 to above policy map
`RTR6(config-pmap-c-que)#exit`	Exit
`RTR6(config-pmap-que)#class type queuing que1`	Add class map que1 to above policy map
`RTR6(config-pmap-c-que)#exit`	Exit
`RTR6(config-pmap-que)#class type queuing que2`	Add class map que2 to above policy map
`RTR6(config-pmap-que)#priority level 0`	configure Priority level 0
`RTR6(config-pmap-c-que)#exit`	Exit
`RTR6(config-pmap-que)#class type queuing que3`	Add class map que3 to above policy map
`RTR6(config-pmap-c-que)#exit`	Exit
`RTR6(config-pmap-que)#policy-map type queuing service`	Create policy map with name service
`RTR6(config-pmap-que)#class type queuing service10`	Add class map service10 to above policy map
`RTR6(config-pmap-que)#priority level 0`	Change priority level 0
`RTR6(config-pmap-c-que)#service-policy queue`	Add policy map queue as service-policy
`RTR6(config-pmap-c-que)#exit`	Exit

`RTR6(config-pmap-que)#class type queuing service20`	Add class map service20 to above policy map
`RTR6(config-pmap-c-que)#service-policy queue`	Add policy map queue as service-policy
`RTR6(config-pmap-c-que)#exit`	Exit
`RTR6(config-pmap-que)#interface xe13`	Configure interface xe13
`RTR6(config-if)#service-policy type queuing output service`	Attach the policy map service to the interface
`RTR6(config-if)#shape rate 1000 mbps`	Shape rate traffic to 1000 mbps
`RTR6(config-if)#exit`	Exit

```

L3VPN- Sub/VLAN interfaces

Figure 18-122 displays a six node topology configured with end to end connectivity from Router 1 to Router 6. The end to end connectivity is established by configuring OSPF, iBGP and LDP configuration in all the routers. We should be able to ping each device from other device from topology. Configure L3VPN with sub interface and VLAN interface configurations on RTR1 and RTR6 and create Qos configuration on RTR6 and verify service queuing.

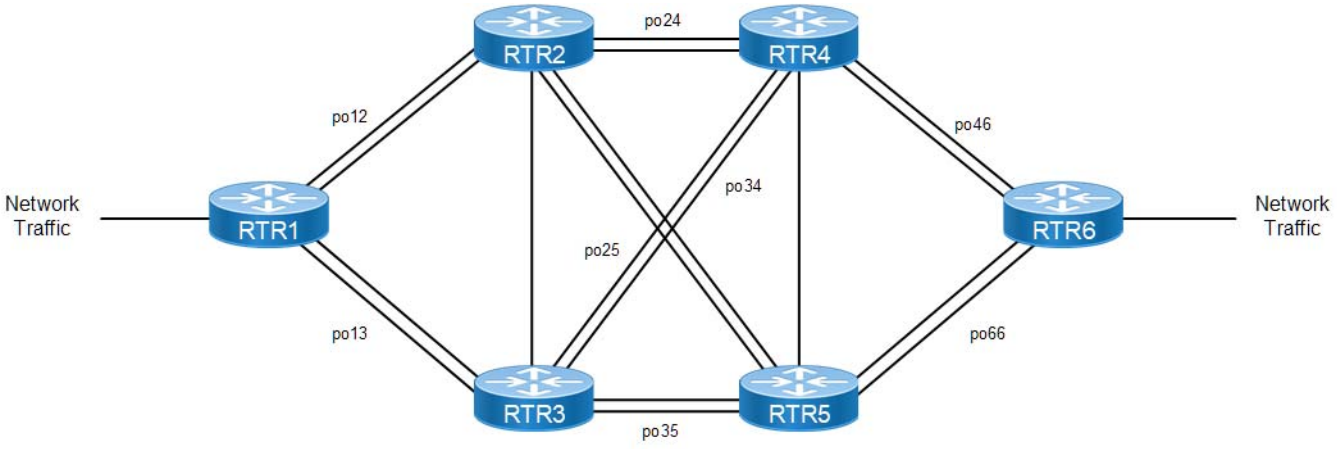

Figure 18-122: Simple Topology

RTR1

`RTR1(config)#ip vrf 3`	Create new vrf with name 3
`RTR1(config-vrf)#rd 2:3`	Create route distinguisher for vrf 3
`RTR1(config-vrf)#route-target both 1:3`	Create route target for vrf 3

`RTR1(config-vrf)#ip vrf 4`	Create new vrf with name 4
`RTR1(config-vrf)#rd 2:4`	Create route distinguisher for vrf 4
`RTR1(config-vrf)#route-target both 1:4`	Create route target for vrf 4
`RTR1(config-vrf)#ip vrf 5`	Create new vrf with name 5
`RTR1(config-vrf)#rd 2:5`	Create route distinguisher for vrf 5
`RTR1(config-vrf)#route-target both 1:5`	Create route target for vrf 5
`RTR1(config-vrf)#ip vrf 6`	Create new vrf with name 6
`RTR1(config-vrf)#rd 2:6`	Create route distinguisher for vrf 6
`RTR1(config-vrf)#route-target both 1:6`	Create route target for vrf 6
`RTR1(config-vrf)#exit`	Exit
`RTR1(config)#interface lo.3`	Configure loopback lo.3
`RTR1(config-if)#ip vrf forwarding 3`	Attach VRF 3 to loopback lo.3 interface
`RTR1(config-if)#interface lo.4`	Configure loopback lo.4
`RTR1(config-if)#ip vrf forwarding 4`	Attach VRF 4 to loopback lo.4 interface
`RTR1(config-if)#interface lo.5`	Configure loopback lo.5
`RTR1(config-if)#ip vrf forwarding 5`	Attach VRF 5 to loopback lo.5 interface
`RTR1(config-if)#interface lo.6`	Configure loopback lo.6
`RTR1(config-if)#ip vrf forwarding 6`	Attach vrf 6 to loopback lo.6 interface
`RTR1(config-if)#exit`	Exit
`RTR1(config)#interface ce52.203`	Create sub interface for ce52 port
`RTR1(config-if)#ip vrf forwarding 3`	Attach vrf 3 to sub int ce52.203
`RTR1(config-if)#ip address 201.203.1.1/24`	Assign ip address 201.203.1.1/24
`RTR1(config-if)#encapsulation dot1q 203`	Encapsulate dot1q VLAN with id 203
`RTR1(config-if)#interface ce52.204`	Create sub interface for ce52 port
`RTR1(config-if)#ip vrf forwarding 4`	Attach vrf 4 to sub int ce52.204
`RTR1(config-if)#ip address 201.204.1.1/24`	Assign ip address 201.204.1.1/24
`RTR1(config-if)#encapsulation dot1q 204`	Encapsulate dot1q VLAN with id 204
`RTR1(config-if)#interface vlan1.205`	Create VLAN interface with id 205
`RTR1(config-if)#ip vrf forwarding 5`	Attach VRF 5 to vlan1.205
`RTR1(config-if)#ip address 201.205.1.1/24`	Assign IP address of 201.205.1.1/24
`RTR1(config-if)#mtu 9216`	Configure MTU of size 9216
`RTR1(config-if)#interface vlan1.206`	Create VLAN interface with id 206
`RTR1(config-if)#ip vrf forwarding 6`	Attach VRF 6 to vlan1.206
`RTR1(config-if)#ip address 201.206.1.1/24`	Assign ip address of 201.206.1.1/24
`RTR1(config-if)#mtu 9216`	Configure MTU of size 9216
`RTR1(config)#router bgp 64512`	Configure router BGP 66512
`RTR1(config-router)#address-family vpnv4 unicast`	Enter into vpnv4 unicast address family
`RTR1(config-router-af)#neighbor 6.6.6.6 activate`	Activate neighbor on vpnv4 unicast
`RTR1(config-router-af)#exit-address-family`	Exit

`RTR1(config-router)#address-family ipv4 vrf 3`	Enter into ipv4 vrf3 address family
`RTR1(config-router-af)#redistribute connected`	Redistribute connected networks into vrf 3
`RTR1(config-router-af)#exit-address-family`	Exit
`RTR1(config-router)#address-family ipv4 vrf 4`	Enter into ipv4 vrf4 address family
`RTR1(config-router-af)#redistribute connected`	Redistribute connected networks into vrf 4
`RTR1(config-router-af)#exit-address-family`	Exit
`RTR1(config-router)#address-family ipv4 vrf 5`	Enter into ipv4 vrf5 address family
`RTR1(config-router-af)#redistribute connected`	Redistribute connected networks into vrf 5
`RTR1(config-router-af)#exit-address-family`	Exit
`RTR1(config-router)#address-family ipv4 vrf 6`	Enter into ipv4 vrf6 address family
`RTR1(config-router-af)#redistribute connected`	Redistribute connected networks into vrf 6
`RTR1(config-router-af)#exit-address-family`	Exit
`RTR1(config-router)#exit`	Exit
`RTR1(config)#interface ce52`	Configure interface ce52
`RTR1(config-if)#load-interval 30`	Configure load interval 30
`RTR1(config-if)#interface ce50`	Configure interface ce50
`RTR1(config-if)#switchport`	Configure port as layer 2 port
`RTR1(config-if)#bridge-group 1`	Configure interface in bridge group 1
`RTR1(config-if)#switchport mode trunk`	Configure interface as trunk port
`RTR1(config-if)#switchport trunk allowed vlan add 205, 206`	Allow only VLANs 205 and 206
`RTR1(config-if)#load-interval 30`	Configure load interval 30

RTR6

`RTR6(config)#ip vrf 3`	Create new vrf with name 3
`RTR6(config-vrf)#rd 1:3`	Create route distinguisher for VRF 3
`RTR6(config-vrf)#route-target both 1:3`	Create route target for VRF 3
`RTR6(config-vrf)#ip vrf 4`	Create new VRF with name 4
`RTR6(config-vrf)#rd 1:4`	Create route distinguisher for VRF 4
`RTR6(config-vrf)#route-target both 1:4`	Create route target for VRF 4
`RTR6(config-vrf)#ip vrf 5`	Create new VRF with name 5
`RTR6(config-vrf)#rd 1:5`	Create route distinguisher for VRF 5
`RTR6(config-vrf)#route-target both 1:5`	Create route target for VRF 5
`RTR6(config-vrf)#ip vrf 6`	Create new VRF with name 6
`RTR6(config-vrf)#rd 1:6`	Create route distinguisher for VRF 6
`RTR6(config-vrf)#route-target both 1:6`	Create route target for VRF 6

RTR6(config-vrf)#exit	Exit
RTR6(config)#interface lo.3	Configure loopback lo.3
RTR6(config-if)#ip vrf forwarding 3	Attach vrf 3 to loopback lo.3 interface
RTR6(config-if)#interface lo.4	Configure loopback lo.4
RTR6(config-if)#ip vrf forwarding 4	Attach vrf 4 to loopback lo.4 interface
RTR6(config-if)#interface lo.5	Configure loopback lo.5
RTR6(config-if)#ip vrf forwarding 5	Attach vrf 5 to loopback lo.5 interface
RTR6(config-if)#interface lo.6	Configure loopback lo.6
RTR6(config-if)#ip vrf forwarding 6	Attach VRF 6 to loopback lo.6 interface
RTR6(config-if)#interface xe13.103	Create sub interface for xe13 port
RTR6(config-if)#ip vrf forwarding 3	Attach VRF 3 to sub int xe13.103
RTR6(config-if)#ip address 101.103.1.1/24	Assign ip address 101.103.1.1/24
RTR6(config-if)#encapsulation dot1q 103	Encapsulate dot1q VLAN with id 103
RTR6(config-if)#interface xe13.104	Create sub interface for xe13.104 port
RTR6(config-if)#ip vrf forwarding 4	Attach VRF 4 to sub int xe13.104
RTR6(config-if)#ip address 101.104.1.1/24	Assign IP address 101.104.1.1/24
RTR6(config-if)#encapsulation dot1q 104	Encapsulate dot1q VLAN with id 104
RTR6(config-if)#interface vlan1.105	Create VLAN interface with id 105
RTR6(config-if)#ip vrf forwarding 5	Attach VRF 5 to vlan1.105
RTR6(config-if)#ip address 101.105.1.1/24	Assign ip address of 101.105.1.1/24
RTR6(config-if)#mtu 9216	Configure MTU of size 9216
RTR6(config-if)#interface vlan1.106	Create VLAN interface with id 106
RTR6(config-if)#ip vrf forwarding 6	Attach VRF 6 to vlan1.106
RTR6(config-if)#ip address 101.106.1.1/24	Assign IP address of 101.106.1.1/24
RTR6(config-if)#mtu 9216	Configure mtu of size 9216
RTR6(config-if)#exit	Exit
RTR6(config)#router bgp 64512	Configure BGP 64512
RTR6(config-router)#address-family vpnv4 unicast	Enter into vpnv4 unicast address family
RTR6(config-router-af)#neighbor 1.1.1.1 activate	Activate neighbor on vpnv4 unicast
RTR6(config-router-af)#exit-address-family	Exit
RTR6(config-router)#address-family ipv4 vrf 3	Enter into ipv4 vrf3 address family
RTR6(config-router-af)#redistribute connected	Redistribute connected networks into VRF 3
RTR6(config-router-af)#exit-address-family	Exit
RTR6(config-router)#address-family ipv4 vrf 4	Enter into ipv4 vrf4 address family
RTR6(config-router-af)#redistribute connected	Redistribute connected networks into vrf 4
RTR6(config-router-af)#exit-address-family	Exit

`RTR6(config-router)#address-family ipv4 vrf 5`	Enter into ipv4 vrf5 address family
`RTR6(config-router-af)#redistribute connected`	Redistribute connected networks into vrf 5
`RTR6(config-router-af)#exit-address-family`	Exit
`RTR6(config-router)#address-family ipv4 vrf 6`	Enter into ipv4 vrf6 address family
`RTR6(config-router-af)#redistribute connected`	Redistribute connected networks into vrf 6
`RTR6(config-router-af)#exit-address-family`	Exit
`RTR6(config-router)#exit`	Exit
`RTR6(config)#interface xe13`	Configure interface xe13
`RTR6(config-if)#load-interval 30`	Configure load interval 30
`RTR6(config-if)#interface xe14`	Configure interface xe14
`RTR6(config-if)#switchport`	Configure port as layer 2 port
`RTR6(config-if)#bridge-group 1`	Configure interface in bridge group 1
`RTR6(config-if)#switchport mode trunk`	Configure interface as trunk port
`RTR6(config-if)#switchport trunk allowed vlan add 105,106`	Allow only vlans105 and 106
`RTR6(config-if)#load-interval 30`	Configure load interval 30
`RTR6(config-if)#exit`	Exit

Provider Bridge

Figure 18-123 displays a six node topology configured with end to end connectivity from Router 1 to Router 6. The end to end connectivity is established by configuring OSPF, iBGP and LDP configuration in all the routers. We should be able to ping each device from other device from topology.

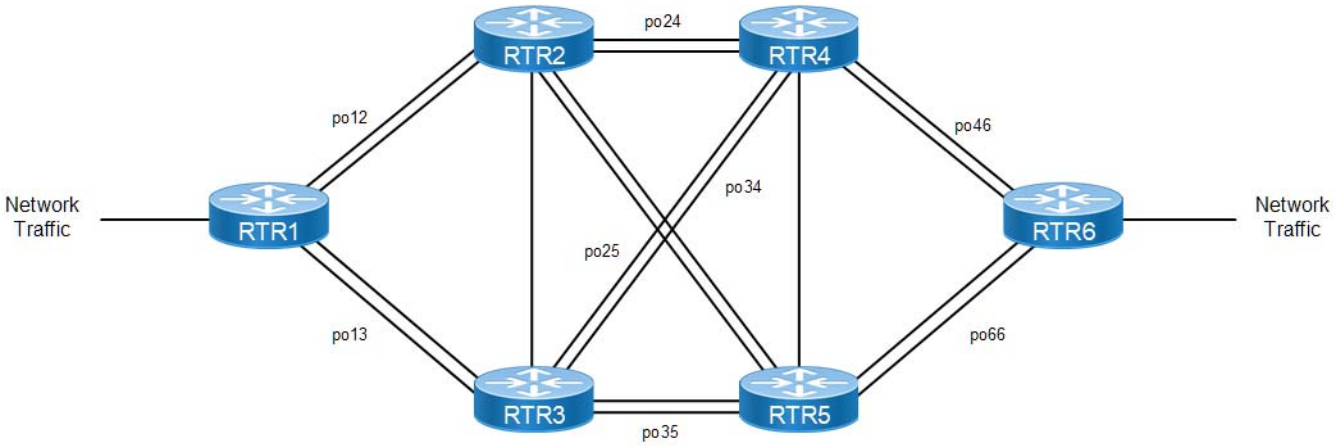

Figure 18-123: Simple Topology

RTR1

`RTR1#configure terminal`	Enter into configure terminal mode
`RTR1(config)#bridge 1 protocol provider-rstp edge`	Configure bridge 1 protocol as provider RSTP edge
`RTR1(config)#vlan database`	Configure VLAN database
`RTR1(config-vlan)#vlan 201-300 type customer bridge 1 state enable`	Configure customer VLANs from 201-300
`RTR1(config-vlan)#vlan 301-400 type service point-point bridge 1 state enable`	Configure service VLANs from 301-400
`RTR1(config-vlan)#cvlan registration table map1 bridge 1`	Create cvlan registration table
`RTR1(config-cvlan-registration)#cvlan 201 svlan 301`	Map 201 cvlan to 301 svlan
`RTR1(config-cvlan-registration)#cvlan 202 svlan 302`	Map 202 cvlan to 302 svlan
`RTR1(config-cvlan-registration)#cvlan 203 svlan 303`	Map 203 cvlan to 303 svlan
`RTR1(config-cvlan-registration)#cvlan 204 svlan 304`	Map 204 cvlan to 304 svlan
`RTR1(config-cvlan-registration)#cvlan 205 svlan 305`	Map 205 cvlan to 305 svlan
`RTR1(config-cvlan-registration)#interface po12`	Configure interface po12
`RTR1(config-if)#switchport`	Configure as layer 2 port
`RTR1(config-if)#bridge-group 1`	Configure interface in bridge group 1
`RTR1(config-if)#switchport mode provider-network`	Configure switchport mode as provider network
`RTR1(config-if)#switchport provider-network allowed vlan add 301-400`	Configure allowed VLAN from 301-400
`RTR1(config-if)#load-interval 30`	Configure load interval 30
`RTR1(config-if)#interface po13`	Configure interface po13
`RTR1(config-if)#switchport`	Configure as layer 2 port
`RTR1(config-if)#bridge-group 1`	Configure interface in bridge group 1
`RTR1(config-if)#switchport mode provider-network`	Configure switchport mode as provider network
`RTR1(config-if)#switchport provider-network allowed vlan add 301-400`	Configure allowed vlan from 301-400
`RTR1(config-if)#load-interval 30`	Configure load interval 30
`RTR1(config-if)#interface xe1`	Configure xe1
`RTR1(config-if)#channel-group 12 mode active`	Add xe1 to po12
`RTR1(config-if)#interface xe2`	Configure xe2
`RTR1(config-if)#channel-group 12 mode active`	Add xe2 to po12
`RTR1(config-if)#interface xe3`	Configure xe3

`RTR1(config-if)#channel-group 13 mode active`	Add xe3 to po13
`RTR1(config-if)#interface xe4`	Configure xe4
`RTR1(config-if)#channel-group 13 mode active`	Add xe4 to po13
`RTR1(config-if)#interface xe15`	Configure interface xe15
`RTR1(config-if)#switchport`	Configure as layer 2 port
`RTR1(config-if)#bridge-group 1`	Configure interface in bridge group 1
`RTR1(config-if)#switchport mode customer-edge trunk`	Configure switchport mode as customer edge trunk
`RTR1(config-if)#switchport customer-edge trunk allowed vlan add 201-300`	Configure allowed vlan from 201-300
`RTR1(config-if)#switchport customer-edge vlan registration map1`	Attach VLAN registration table map 1 to xe15
`RTR1(config-if)#load-interval 30`	Configure load interval 30
`RTR1(config-if)#exit`	Exit

RTR2

`RTR2#configure terminal`	Configure terminal
`RTR2(config)#bridge 1 protocol provider-rstp`	Configure bridge 1 protocol as provider rstp edge
`RTR2(config)#vlan database`	VLAN database
`RTR2(config-vlan)#vlan 301-400 type service point-point bridge 1 state enable`	Configure service vlans from 301-400
`RTR2(config-vlan)#interface po12`	Configure interface po12
`RTR2(config-if)#switchport`	Configure as layer 2 port
`RTR2(config-if)#bridge-group 1`	Configure interface in bridge group 1
`RTR2(config-if)#switchport mode provider-network`	Configure switchport mode as provider network
`RTR2(config-if)#switchport provider-network allowed vlan add 301-400`	Configure allowed vlan from 301-400
`RTR2(config-if)#load-interval 30`	Configure load interval 30
`RTR2(config-if)#interface po24`	Configure interface po24
`RTR2(config-if)#switchport`	Configure as layer 2 port
`RTR2(config-if)#bridge-group 1`	Configure interface in bridge group 1
`RTR2(config-if)#switchport mode provider-network`	Configure switchport mode as provider network
`RTR2(config-if)#switchport provider-network allowed vlan add 301-400`	Configure allowed vlan from 301-400
`RTR2(config-if)#load-interval 30`	Configure load interval 30
`RTR2(config-if)#interface po25`	Configure interface po25
`RTR2(config-if)#switchport`	Configure as layer 2 port
`RTR2(config-if)#bridge-group 1`	Configure interface in bridge group 1
`RTR2(config-if)#switchport mode provider-network`	Configure switchport mode as provider network

RTR2(config-if)#switchport provider-network allowed vlan add 301-400	Configure allowed vlan from 301-400
RTR2(config-if)#load-interval 30	Configure load interval 30
RTR2(config-if)#interface xe1	Configure xe1
RTR2(config-if)#channel-group 12 mode active	Add xe1 to po12
RTR2(config-if)#interface xe2	Configure xe2
RTR2(config-if)#channel-group 12 mode active	Add xe2 to po12
RTR2(config-if)#interface xe8	Configure xe8
RTR2(config-if)#channel-group 25 mode active	Add xe8 to po25
RTR2(config-if)#interface xe9	Configure xe9
RTR2(config-if)#channel-group 25 mode active	Add xe9 to po25
RTR2(config-if)#interface xe14	Configure xe14
RTR2(config-if)#channel-group 24 mode active	Add xe14 to po24
RTR2(config-if)#interface xe15	Configure xe15
RTR2(config-if)#channel-group 24 mode active	Add xe15 to po24
RTR2(config)#exit	Exit

RTR3

RTR3#config term	Configure terminal
RTR3(config)#bridge 1 protocol provider-rstp	Configure bridge 1 protocol as provider rstp edge
RTR3(config)#vlan database	Configure VLAN database
RTR3(config-vlan)#vlan 301-400 type service point-point bridge 1 state enable	Configure service VLANS from 301-400

CHAPTER 19 Queue Compensation

The size of packets transmitted may vary from the size of packets queued in ingress and egress queues. Contributing factors are:

1. Ethernet Overhead

   Fixed size, typically 20-bytes

2. Internal DRAM CRC

   Fixed size, 2-byte CRC

3. Packet editing resulting from Packet Processing

   Size may vary per queue or per packet

   Network header termination (i.e., Layer-3 link layer termination from routing, MPLS/IP tunnel termination, VLAN Tag removal)

   Network header encapsulation (i.e., Layer-3 link layer encapsulation, MPLS/IP tunnel initiation, Vlan tag addition)

These bytes need to be adjusted to achieve the proper egress rate. Hence, compensation is used to adjust this byte difference in order to achieve the expected egress rate.

The default compensation for all queues is set to -22 internally (Ethernet overhead + internal CRC). This is as per the internal headers in the packet pipeline.

When an attachment-circuit is created on a port the compensation is updated as shown in Table 19-82.

Table 19-82: Compensation updates

AC ingress operation	Compensation
POP	-38
NONE/Translate	-42 (defaults)
PUSH	-46

Note: It is the operator's responsibility to update the compensation if required per application.

The user can configure compensation on the class-maps matching services for service queues, and class-map for “class-default-q” for port queues.

CLI: `compensation <-64-64>`

For example:

```
class-map type queuing data
 match queue 0
!
class-map type queuing service1
 match service-template ETH-2016
!
class-map type queuing service2
 match service-template ETH-2017
!
class-map type queuing signal
 match queue 3
```

```
!
class-map type queuing voice
 match queue 1
!
policy-map type queuing configPolicy1
 class type queuing class-default-q
  exit
 class type queuing data
  exit
 class type queuing signal
  exit
 class type queuing voice
  exit
!
policy-map type queuing customer1
 class type queuing service1
  compensation -20
  service-policy configPolicy1
 class type queuing class-default-q
  compensation -20
  exit
!
interface xe11
 service-policy type queuing output customer1
```

CHAPTER 20 Hierarchical Traffic Policing

Basic traffic policing is explained in Chapter 3, *Traffic Policing*, which covers single-level policing. The Qumran device support two level hierarchical policing in addition to single level traffic policing (Hierarchical policing is also in compliance with RFC 2697 and RFC 4115).

Hierarchical policing ensures traffic policing in two levels in serial mode. Traffic is policed with a “child policer” configuration first, and then policed at a second level, the “parent policer” configuration. Thus, traffic is treated with two levels of policing.

Hierarchical policing will be useful when traffic to be policed per service and additionally to be policed per customers of that particular service. Hierarchical policing is useful when multiple streams (such as voice, data) of customer traffic to be policed and additionally, traffic to be policed per customer. Configuration considerations for hierarchical policing are same as mentioned in Chapter 3, *Traffic Policing*.

Configuring Hierarchical Traffic Policing

Command to configure policing on a class remains same as explained in Chapter 3, *Traffic Policing*.

In addition to the commands explained in Chapter 1, *Quality of Service (QoS)* and Chapter 2, *Configuring a QoS Policy-map*, binding a child policy-map to a parent class is done using the following command:

```
service-policy NAME
```

Notice that `NAME` represents the name of the child qos policy-map. This command is configurable on the class mode as shown in the example below:

```
(config)#policy-map Pmap-Parent-1
(config-pmap-qos)#class Cmap-Parent-1
(config-pmap-c-qos)#service-policy Pmap-Child-1
(config-pmap-c-qos)#exit
```

An example of creating parent and child class-maps and policy-maps, and configuring them for hierarchical policing is shown below:

Note: the qos-policer TCAM group must be enabled before binding a parent policy-map to an interface. For more information about the hardware filter groups, refer to the *Hardware-profile Filters* and the *Show Hardware-profile Filters* sections in the *Qumran Command Reference Guide.*

In the following example, traffic streams on VLAN ID 10, where one stream with CoS value 1 and another stream with CoS value 2 (received on interface xe1) are policed to a total of 40 mbps with 10 mbps of traffic being marked green for stream1 at 20 mbps, and traffic marked green for stream2. The remaining 10 mbps of traffic from stream1 and stream2 is marked yellow. Any remaining traffic will be dropped at ingress.

```
(config)#qos enable
(config)#class-map CUST-10
(config-cmap-qos)#match vlan 10
(config-cmap-qos)#exit
(config)#class-map CUST-10-C1
(config-cmap-qos)#match cos 1
(config-cmap-qos)#exit
(config)#class-map CUST-10-C2
(config-cmap-qos)#match cos 2
(config-cmap-qos)#exit
(config)#policy-map PC-CUST-10
(config-pmap-qos)#class CUST-10-C1
```

```
(config-pmap-c-qos)#police cir 10 mbps eir 30 mbps
(config-pmap-c-qos)#exit
(config-pmap-qos)#class CUST-10-C2
(config-pmap-c-qos)#police cir 20 mbps eir 20 mbps
(config-pmap-c-qos)#exit
(config-pmap-qos)#class class-default
(config-pmap-c-qos)#police cir 10 mbps eir 30 mbps
(config-pmap-c-qos)#exit
(config-pmap-qos)#exit
(config)#policy-map P-CUST-10
(config-pmap-qos)#class CUST-10
(config-pmap-c-qos)#police cir 40 mbps
(config-pmap-c-qos)#service-policy PC-CUST-10
(config-pmap-c-qos)#exit
(config-pmap-qos)#exit
(config)#hardware-profile filter qos-policer enable
(config)#interface xe1
(config-if)#service-policy type qos input P-CUST-10
(config-if)#exit
```

Configuring Hierarchical Policing per Attachment Circuit

In this section, a configuration example is provided for the use-case of configuring traffic policing per attachment circuit with additional traffic policing based on the class of traffic. The configuration helps in providing overall traffic policing per attachment circuit and additionally ensures that different classes of traffic are policed. Total CIR configurations for child classes must be ensured to match the police rate of parent and EIR values for child can be configured to take the available bandwidth when one or more child traffic is not received at any point in time.

Topology

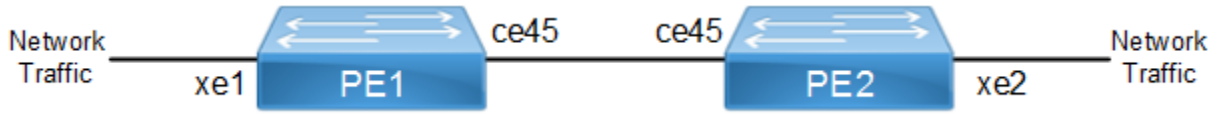

Figure 20-124: Topology for per-AC hierarchical policing

PE1

`PE1#configure terminal`	Enter configure terminal mode
`PE1(config)#hardware-profile filter ingress-ipv6 enable`	Enabling Ingress IPv6 group for IPv6 feature support
`PE1(config)#hardware-profile filter qos-policer enable`	Enabling Ingress extended QOS group for hierarchical policer
`PE1(config)#qos enable`	Enabling QoS
`PE1(config)#qos statistics`	Enabling Qos statistics
`PE1(config)#mpls l2-circuit VPWS-VLAN-200 2000200 21.21.21.21`	Create an instance of an MPLS layer 2 virtual circuit

PE1(config)#mpls l2-circuit VPWS-VLAN-300 2000300 21.21.21.21	Create an instance of an MPLS layer 2 virtual circuit
PE1(config)#mpls lsp-model uniform	Configure the MPLS LSP model as Uniform.
PE1(config)#service-template VPWS-Vlan200-Service	Enabling Service Template
PE1(config-svc)#match outer-vlan 200	Match outer vlan 200
PE1(config-svc)#rewrite ingress translate 100 outgoing-tpid dot1.q	Enabling command to configure a match VLAN action for a service template
PE1(config-svc)#exit	Exit mode
PE1(config)#service-template VPWS-Vlan300-Service	Enabling Service Template
PE1(config-svc)#match outer-vlan 300	Match outer vlan 300<null>
PE1(config-svc)#rewrite ingress translate 4000 outgoing-tpid dot1.q	Enabling command to configure a match VLAN action for a service template
PE1(config-svc)#exit	Exit mode
PE1(config)#class-map c0	Enter Class-map mode
PE1(config-cmap-qos)#match cos 0	Matching cos value inside class map
PE1(config-cmap-qos)#exit	Exit mode
PE1(config)#class-map c1	Enter Class-map mode
PE1(config-cmap-qos)#match cos 1	Matching cos value inside class map
PE1(config-cmap-qos)#exit	Exit mode
PE1(config)#class-map c2	Enter Class-map mode
PE1(config-cmap-qos)#match cos 2	Matching cos value inside class map
PE1(config-cmap-qos)# exit	Exit mode
PE1(config)#class-map c3	Enter Class-map mode
PE1(config-cmap-qos)#match cos 3	Matching cos value inside class map
PE1(config)#class-map cp1	Enter Class-map mode
PE1(config-cmap-qos)#match vlan 200	Matching vlan inside class map
PE1(config-cmap-qos)#exit	Exit mode
PE1(config)#class-map cp2	Enter Class-map mode
PE1(config-cmap-qos)#match vlan 300	Matching vlan inside class map
PE1(config-cmap-qos)#exit	Exit mode
PE1(config)#policy-map child	Enter policy-map mode
PE1(config-pmap-qos)#class c0	Assign Class c0 to Policy-map child
PE1(config-pmap-c-qos)#police cir 50 mbps eir 150 mbps	Police packets @ Committed information rate 50 mbps
PE1(config-pmap-c-qos)#exit	Exit mode
PE1(config-pmap-qos)#class c1	Assign Class c1 to Policy-map child
PE1(config-pmap-c-qos)#police cir 50 mbps eir 150 mbps	Police packets @ Committed information rate 50 mbps
PE1(config-pmap-c-qos)#exit	Exit mode
PE1(config-pmap-qos)#class c2	Assign Class c2 to Policy-map child
PE1(config-pmap-c-qos)#police cir 50 mbps eir 150 mbps	Police packets @ Committed information rate 50 mbps

PE1(config-pmap-c-qos)#exit	Exit mode
PE1(config-pmap-qos)#class c3	Assign Class c3 to Policy-map child
PE1(config-pmap-c-qos)#police cir 50 mbps eir 150 mbps	Police packets @ Committed information rate 50 mbps
PE1(config-pmap-c-qos)#exit	Exit mode
PE1(config-pmap-qos)#policy-map parent	Enter policy-map mode
PE1(config-pmap-qos)#class cp1	Assign Class cp1 to Policy-map parent
PE1(config-pmap-c-qos)#police cir 200 mbps	Police packets @ Committed information rate 200 mbps
PE1(config-pmap-c-qos)#service-policy child	Attaching child policy to Parent
PE1(config-pmap-c-qos)#exit	Exit mode
PE1(config-pmap-qos)#class cp2	Assign Class cp2 to Policy-map child
PE1(config-pmap-c-qos)#police cir 200 mbps	Police packets @ Committed information rate 200 mbps
PE1(config-pmap-c-qos)#service-policy child	Attaching child policy to Parent
PE1(config-pmap-c-qos)#exit	Exit mode
PE1(config-pmap-qos)#exit	Exit from Policy Map
PE1(config)#router ldp	Enter the Router LDP mode.
PE1(config-router)#targeted-peer ipv4 21.21.21.21	Configure targeted peer
PE1(config-router-targeted-peer)#<null>exit-targeted-peer-mode	Exit Targeted Peer Mode
PE1(config-router)#transport-address ipv4 11.11.11.11	Configure transport address
PE1(config-router)#exit	Exit mode
PE1(config)#interface ce45	Entering Interface Mode
PE1(config-if)#ip address 1.1.1.1/24	Assigning IP Address to interface
PE1(config-if)#label-switching	Enabling Label Switching on the interface.
PE1(config-if)#enable-ldp ipv4	Enabling LDP
PE1(config-if)#exit	Exit mode
PE1(config)#interface lo	Entering loopback Interface Mode
PE1(config-if)#ip address 11.11.11.11/32 secondary	Assigning IP Address to interface
PE1(config-if)#exit	Exit mode
PE1(config)#interface xe2	Entering Interface Mode
PE1(config-if)#switchport	Enabling the Interface as Switchport
PE1(config-if)#mpls-l2-circuit VPWS-VLAN-200 service-template VPWS-Vlan200-Service	Bind the interface to the VC and add the service-template.
PE1(config-if)#mpls-l2-circuit VPWS-VLAN-300 service-template VPWS-Vlan300-Service	Bind the interface to the VC and add the service-template.
PE1(config-if)#service-policy type qos input parent	Assign service-policy to interface on in-direction
PE1(config-if)#exit	Exit mode
PE1(config)#router ospf	Configure the routing process and The Process ID should be a unique positive integer identifying the routing process

PE1(config-router)#network 1.1.1.0/24 area 0.0.0.0	Define the interface on which OSPF runs and associate the area ID (0) with the interface.
PE1(config-router)#network 11.11.11.11/32 area 0.0.0.0	Define the interface on which OSPF runs and associate the area ID (0) with the interface.
PE1(config-router)#exit	Exit Router Ospf MOde

PE2 Configuration

PE2#configure terminal	Enter configure terminal mode
PE2(config)#hardware-profile filter ingress-ipv6 enable	Enabling Ingress IPv6 group for IPv6 feature
PE2(config)#hardware-profile filter qos-policer enable	Enabling Ingress extended QOS group for hierarchical policer
PE2(config)#qos enable	Enabling QoS
PE2(config)#qos statistics	Enabling Qos statistics
PE2(config)#mpls l2-circuit VPWS-VLAN-200 2000200 11.11.11.11	Create an instance of an MPLS layer 2 virtual circuit
PE2(config)#mpls l2-circuit VPWS-VLAN-300 2000300 11.11.11.11	Create an instance of an MPLS layer 2 virtual circuit
PE2(config)#mpls lsp-model uniform	Configure the MPLS LSP model as Uniform.
PE2(config)#service-template VPWS-Vlan200-Service	Enabling Service Template
PE2(config-svc)#match outer-vlan 200	Match outer vlan 200
PE2(config-svc)#rewrite ingress translate 100 outgoing-tpid dot1.q	Enabling command to configure a match VLAN action for a service template
PE2(config-svc)#exit	Exit mode
PE2(config)#service-template VPWS-Vlan300-Service	Enabling Service Template
PE2(config-svc)#match outer-vlan 300	Match outer vlan 300
PE2(config-svc)#rewrite ingress translate 4000 outgoing-tpid dot1.q	Enabling command to configure a match VLAN action for a service template
PE2(config-svc)#exit	Exit mode
PE2(config)#class-map c0	Enter Class-map mode
PE2(config-cmap-qos)# match cos 0	Matching cos value inside class map
PE2(config-cmap-qos)#exit	Exit mode
PE2(config)#class-map c1	Enter Class-map mode
PE2(config-cmap-qos)#match cos 1	Matching cos value inside class map
PE2(config-cmap-qos)#exit	Exit mode
PE2(config)#class-map c2	Enter Class-map mode
PE2(config-cmap-qos)#match cos 2	Matching cos value inside class map
PE2(config-cmap-qos)#exit	Exit mode
PE2(config)#class-map c3	Enter Class-map mode
PE2(config-cmap-qos)#match cos 3	Matching cos value inside class map
PE2(config-cmap-qos)#exit	Exit mode

PE2(config)#class-map cp1	Enter Class-map mode
PE2(config-cmap-qos)#match vlan 200	Matching vlan inside class map
PE2(config-cmap-qos)#exit	Exit mode
PE2(config)#class-map cp2	Enter Class-map mode
PE2(config-cmap-qos)#match vlan 300	Matching vlan inside class map
PE2(config-cmap-qos)#exit	Exit mode
PE2(config)#policy-map child	Enter policy-map mode
PE2(config-pmap-qos)#class c0	Assign Class c0 to Policy-map child
PE2(config-pmap-c-qos)#police cir 50 mbps eir 150 mbps	Police packets @ Committed information rate 50 mbps
PE2(config-pmap-c-qos)#exit	Exit mode
PE2(config-pmap-qos)#class c1	Assign Class c1 to Policy-map child
PE2(config-pmap-c-qos)#police cir 50 mbps eir 150 mbps	Police packets @ Committed information rate 50 mbps
PE2(config-pmap-c-qos)#exit	Exit mode
PE2(config-pmap-qos)#class c2	Assign Class c2 to Policy-map child
PE2(config-pmap-c-qos)#police cir 50 mbps eir 150 mbps	Police packets @ Committed information rate 50 mbps
PE2(config-pmap-c-qos)#exit	Exit mode
PE2(config-pmap-qos)#class c3	Assign Class c3 to Policy-map child
PE2(config-pmap-c-qos)#police cir 50 mbps eir 150 mbps	Police packets @ Committed information rate 50 mbps
PE2(config-pmap-c-qos)#exit	Exit mode
PE2(config-pmap-qos)#policy-map parent	Enter policy-map mode
PE2(config-pmap-qos)#class cp1	Assign Class cp1 to Policy-map parent
PE2(config-pmap-c-qos)#police cir 200 mbps	Police packets @ Committed information rate 200 mbps
PE2(config-pmap-c-qos)#service-policy child	Attaching child policy to Parent
PE2(config-pmap-c-qos)#exit	Exit mode
PE2(config-pmap-qos)#class cp2	Assign Class cp2 to Policy-map child
PE2(config-pmap-c-qos)#police cir 200 mbps	Police packets @ Committed information rate 200 mbps
PE2(config-pmap-c-qos)#service-policy child	Attaching child policy to Parent
PE2(config-pmap-c-qos)#exit	Exit mode
PE2(config-pmap-qos)#exit	Exit from Policy Map
PE2(config)#router ldp	Enter the Router LDP mode
PE2(config-router)#targeted-peer ipv4 11.11.11.11	Configure targeted peer
PE2(config-router-targeted-peer)#exit-targeted-peer-mode	Exit Targeted Peer Mode
PE2(config-router)# transport-address ipv4 21.21.21.21	Configure transport address
PE2(config-router)#exit	Exit mode
PE2(config)#interface ce45	Entering Interface Mode
PE2(config-if)#ip address 1.1.1.2/24	Assigning IP Address to interface

PE2(config-if)#label-switching	Enabling Label Switching on the interface.
PE2(config-if)#enable-ldp ipv4	Enabling LDP
PE2(config-if)#exit	Exit mode
PE2(config)#interface lo	Entering loopback Interface Mode
PE2(config-if)#ip address 21.21.21.21/32 secondary	Assigning IP Address to interface
PE2(config-if)#exit	Exit interface mode
PE2(config)#interface xe1	Entering Interface Mode
PE2(config-if)#switchport	Enabling the Interface as Switch port
PE2(config-if)#mpls-l2-circuit VPWS-VLAN-200 service-template VPWS-Vlan200-Service	Bind the interface to the VC and add the service-template.
PE2(config-if)#mpls-l2-circuit VPWS-VLAN-300 service-template VPWS-Vlan300-Service	Bind the interface to the VC and add the service-template.
PE2(config-if)#service-policy type qos input parent	Assign service-policy to interface on in-direction
PE2(config-if)#exit	Exit interface mode
PE2(config)#router ospf	Configure the routing process and The Process ID should be a unique positive integer identifying the routing process
PE2(config-router)#network 1.1.1.0/24 area 0.0.0.0	Define the interface on which OSPF runs and associate the area ID (0) with the interface.
PE2(config-router)#network 21.21.21.21/32 area 0.0.0.0	Define the interface on which OSPF runs and associate the area ID (0) with the interface.
PE2(config-router)#exit	Exit Router OSPF mode

Validation

PE1

Validate LDP session using following show command:

```
PE1#show ldp session
Peer IP Address           IF Name    My Role    State      KeepAlive  UpTime
21.21.21.21               ce45       Passive   OPERATIONAL   30    00:05:40
```

Validate virtual circuit status using following command:

```
PE1#show mpls vc-table
VC-ID    VID  Inner-VID  Ac-Intf  Nw-Intf  Out Label  Tunnel-Label  Nexthop      Status
2000200  N/A  N/A        xe2      ce45     24320      3             21.21.21.21  Active
2000300  N/A  N/A        xe2      ce45     24321      3             21.21.21.21  Active
```

Validate QoS configuration and statistics using below commands:

```
PE1#show policy-map interface xe2

Interface xe2
Type QoS statistics status : enabled
```

```

```

CHAPTER 21 Subinterface Queuing

In Qumran devices, every physical port has default eight priority queues and subinterface has default 4 priority queues. Physical port queues are created during initialization while the subinterface queues will be created/deleted when encap is set/unset respectively on subinterface. Whenever QoS feature is enabled, all priority queues of the physical ports/ subinterafce will be configured with certain default egress queuing parameters.

In order to customize the treatment on the priority queues, queuing policy-map infrastructure need to be used.

Configuring Subinterface Queues

Subinterface queues are nothing different then the physical ports queues expect that number of queues assigned to a subinterface can be set via profile and by-default profile1 is set which sets 4 queues to be created for services.

User can configure the service-queue profile via cli "hardware-profile service-queue (profile1 | profile2)".

Profile1 supports 4 new queues creation for services,which is also a default profile. Profile2 supports 8 new queues creation for services.

These queues will be created or deleted when the encap is set or unset on a subinterface respectively. Like and other interface, subinterface has a default ingress egress mapping profile. i.e.dscp-to-queue and dscp-color-to-dscp respectively. Subinterface has default queuing-policy in order to support QoS treatment on the queues.

Mapping profiles (dscp-to-queue and dscp-color-to-dscp) maps packets dscp to/from 8 traffic classes. When the hardware-queues created are 4, 8 traffic classes will be mapped to these 4 hardware-queues implicitly as shown in Table 21-83:

Table 21-83: Traffic class to queue mapping

Traffic class	Queue
0	0
1, 2, 3	1
4, 5	2
6-7	3

This map can be checked via this command:

```
show queue remapping
```

Output:

```
Port queue remapping:
+------------+-----------------------+
|  Queue/tc  |     hardware-queue    |
+------------+-----------------------+
|      0     |           0           |
|      1     |           1           |
|      2     |           2           |
|      3     |           3           |
|      4     |           4           |
|      5     |           5           |
|      6     |           6           |
|      7     |           7           |
```

```
+------------+-----------------------+

Service queue remapping:
+------------+-----------------------+
|  Queue/tc  |     hardware-queue    |
+------------+-----------------------+
|      0     |           0           |
|      1     |           1           |
|      2     |           1           |
|      3     |           1           |
|      4     |           2           |
|      5     |           2           |
|      6     |           3           |
|      7     |           3           |
+------------+-----------------------+
```

When the number of profile 2 is active, number of new queues created will be 8 and the traffic class to hardware queues map will be one to one.

This map can be checked via this command:

```
    show queue remapping
```

Output:

```
Port queue remapping:
+------------+-----------------------+
|  Queue/tc  |     hardware-queue    |
+------------+-----------------------+
|      0     |           0           |
|      1     |           1           |
|      2     |           2           |
|      3     |           3           |
|      4     |           4           |
|      5     |           5           |
|      6     |           6           |
|      7     |           7           |
+------------+-----------------------+

Service queue remapping:
+------------+-----------------------+
|  Queue/tc  |     hardware-queue    |
+------------+-----------------------+
|      0     |           0           |
|      1     |           1           |
|      2     |           2           |
|      3     |           3           |
|      4     |           4           |
|      5     |           5           |
|      6     |           6           |
|      7     |           7           |
+------------+-----------------------+
```

Configuring Default Queuing Policy-Map

When the QoS feature is enabled, all subinterfaces is supplied with a default policy-map of queuing type. The default policy-map is created with the name "default-subif-out-policy" which is reserved and modifying parameters in this policy-map is reflected on all subinterfaces that do not have customized queuing policy-maps. Customized queuing policy-maps can be created and bound to subinterface to treat subinterface differently from the default configuration.

Default queuing-policy can be accessed via following cli:

```
policy-map type queuing default subif-default-out-policy
```

Classes mapped to default queues can be accessed via following cli:

```
class type queuing default (q0|q1|q2|q3)
```

User can configure all the queue parameters like shaping, scheduling, wred, taildrop same as on port. Show commands to verify the config and stats are same. For these configurations please check respective chapters as described in the document.

Displaying Policy-Map Configuration

```
(config)#show pol in xe11.1

Interface xe11.1

Type Queuing policy-map : subif-default-out-policy

Class-map (queuing): q0
 shape 1000000 kbps (inherited)
 priority level 0
 queue-limit 1253376 bytes/10 ms (default)

Class-map (queuing): q1
 shape 1000000 kbps (inherited)
 priority level 1
 queue-limit 1253376 bytes/10 ms (default)
      Output
         Total        : 4109055 packets, 279534060 bytes
         Green        : 4120123 packets, 280222424 bytes
         Yellow       : 0 packets, 0 bytes
      Rate            : 768646.000 kbps

Class-map (queuing): q2
 shape 1000000 kbps (inherited)
 priority level 2
 queue-limit 1253376 bytes/10 ms (default)

Class-map (queuing): q3
 shape 1000000 kbps (inherited)
 priority level 3
 queue-limit 1253376 bytes/10 ms (default)
```

Creating a User-Defined Queuing Policy-Map

Qumran supports the creation of customized policy-map in which all 4 priority queues can be accessed. The following is the command to create a customized default policy-map:

```
(no|) policy-map type queuing NAME
```

Class-maps can be configured matching queues via following cli:

```
(no|) class-map type queuing NAME
```

Match queue/queues in the class-map via following cli :

```
(no|) match queue <0-7>
```

Note: The match queue range 0-7 is valid only for port queues classification.

For service queues/subinterface, the valid range is 0-3.

Once the policy-map and class-maps are configured, class-maps can be configured in the policy-map with the following command:

```
class type queuing NAME
```

Binding a User-Defined Queuing Policy-Map

Customized queuing policy-maps take affect only when the configuration is bound to an interface. Queuing policy-maps can be bound to the port with the following command:

```
service-policy type queuing output NAME
```

Where NAME represents the name of the queuing policy-map.

For example:

```
class-map type queuing data
 match queue 0
!
class-map type queuing signal
 match queue 3
!
class-map type queuing voice
 match queue 1
!
policy-map type queuing configPolicy1
 class type queuing class-default-q
  exit
 class type queuing data
  exit
 class type queuing signal
  exit
 class type queuing voice
  exit
!
interface xe11.1
 service-policy type queuing output configPolicy1
```

Queue(s) which are not matched in any class in a user-defined policy-map, will be mapped to Class-default-q by default. This class-default-q is a by-default created class in a user-defined policy-map.

Displaying Policy-Map Configuration

```
(config-if)#do show policy-map in xe11.1

Interface xe11.1

Type Queuing policy-map : configPolicy1

Class-map (queuing): class-default-q
 shape 1000000 kbps (inherited)
 wfq-queue weight 1
 queue-limit 1253376 bytes/10 ms (default)
 match queue 2

Class-map (queuing): data
 shape 1000000 kbps (inherited)
 wfq-queue weight 1
 queue-limit 1253376 bytes/10 ms (default)
 match queue 0

Class-map (queuing): signal
 shape 1000000 kbps (inherited)
 wfq-queue weight 1
 queue-limit 1253376 bytes/10 ms (default)
 match queue 3

Class-map (queuing): voice
 shape 1000000 kbps (inherited)
 wfq-queue weight 1
 queue-limit 1253376 bytes/10 ms (default)
 match queue 1
      Output
         Total        : 2321147 packets, 157909736 bytes
         Green        : 2337514 packets, 158952312 bytes
         Yellow       : 0 packets, 0 bytes
      Rate            : 773130.375 kbps
```

Displaying Policy-Map Rate Statistics

```
#show policy-map statistics type queuing rate mbps
+--------------------------------+--------------------+
|            Class-map           |    Rate (in mbps)  |
+--------------------------------+--------------------+
xe11.1

+--------------------------------+--------------------+
xe11.1
 voice (q1)                       0.774
```

Displaying Interface Queue Counters

```
#show interface xe11.1 counters queue-stats
E - Egress, I - Ingress, Q-Size is in bytes
+-----------------+--------+----------+-----------+-----------------+--------------+
| Queue/Class-map | Q-Size |  Tx pkts | Tx bytes  |  Dropped pkts   | Dropped bytes|
+-----------------+--------+----------+-----------+-----------------+--------------+
q0             (E) 1253376  0          0             0                 0
q1             (E) 1253376  1402466359 95367712820   0                 0
q2             (E) 1253376  0          0             0                 0
q3             (E) 1253376  0          0             0                 0
```

Configuration Considerations

- Max 1 level of user defined hierarchy is supported on subinterface.
- Only match queue is allowed in the class in user-define queuing policy-map.
- In user-defined policy-map, all the classes will be in wfq scheduling manner.
- Class-default-q is a self-created class map as part a policy map. It cannot be created nor be destroyed. It will be displayed only when user access it. Executing command "no class-default-q", will un-configure all the configurations of class-default-q.
- User can configure all queuing parameters like weight, priority, queue-limit, wred and shape in a class inside policy.
- Valid match queue and the priority range is 0-3.
- Update is possible in the policy-map except the update of match criteria. Once the class with some match criteria is used in a policy-map, it cannot be updated.
- Subinterface queuing can be achieved via vlan-shaping (match interface) as well as via default queues.
- User-defined policy with match subinterface can only be attached on parent interface if subinterface is not attached to user-defined policy-map.
- If user-defined policy with match subinterface is attached on parent interface, sub-interface's default policy-map and port shaper will be removed implicitly from subinterface.
- If the user-defined-policy is applied on parent interface matching subinterface, traffic will go to the queues created via user-defined-service-policy and the queue stats for subinterface will only be displayed via service-policy. The subinterfaces not matched in the user-defined-service policy will go to their own queues only and not to class-default as happens in case of vlan shaping.

- On encap delete from subinterface, all the qos configuration will be removed implicitly from the subinterafce.
- If the port shaper is applied on parent port and on subinterface as well, minimum shape rate will take effect.
- Queue shape percent for subinterface queues, will be calculated as in following manner:
- Percentage will be calculated from the Effective Max speed, which will be calculated as follows:

    max_speed = parent_ifp->speed.

  If shaper is applied on parent port:

    max_speed = parent_port_shaper

  If shaper is applied on subinterface:

    max_speed = subinterface_shaper

This document contains this chapter:

CHAPTER 23 Quality of Service Commands

This chapter is a reference for the ingress Quality of Service (QoS) and hierarchical QoS.

- qos statistics
- qos untagged-priority
- queue-limit
- random-detect
- queue shaper
- port shaper
- service-policy type qos
- service-policy type queuing
- set cos
- set dscp
- set precedence
- set queue
- show class-map
- show interface counters
- show policy-map
- show policy-map interface
- show qos-profile
- show qos-profile interface
- show queuing interface
- show running-config qos
- storm-control
- tust dscp
- wfq-queue weight
- vc-qos map-profile
- vpls-qos map-profile

class-map type qos

Use this command to create a class-map of type qos.

Use the no command to remove a class-map.

Note: Class-map without any match qualification behaves similar to default class by matching all the packets on the interface it is attached via service policy.

Note: In a class-map, adding or deleting match criteria will have silent exit and will not proceed with operation.

Note: In match-all class-map, only single value with any criteria can exist. Adding new value for the existing criteria will update the same rule. Multiple values with the same criteria can be added in the “match-any” class-map

Command Syntax

```
class-map (type qos|) (match-any|match-all|) NAME
no class-map (type qos|) (match-any|match-all|) NAME
```

Parameters

NAME	Specify the class map name (Max Size 32)
match-any	Match any parameter (boolean OR)
match-all	Match all parameters (boolean AND)

Default

By default, match type is match-all for any class-map

Command Mode

Configuration Mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
#configure terminal
(config)# class-map type qos C_QOS1
```

class type qos

Use this command to add a QoS class-map to a qos policy map.

Use the `no command` to remove a QoS class-map from the policy map.

Note: Priority of class in policy-map is as follow:

- Match-all" class-maps will have priorities equal to number of match types specified in class-map “Match-any.”
- Will have lowest priority which will be the same as priority of “match-all” with one match type.
- Only policer action is supported in the class having “match access-grp” criteria in match-any class-map.

Command Syntax

```
class (type qos|) (NAME|class-default)
no class (type qos|) (NAME|class-default)
```

Parameters

NAME	Specify the class map name

Default

By default, class is type qos

Command Mode

Policy-map mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)#
(config)#policy-map type qos PP
(config-pmap-que)#class type qos C_PP_1
```

class type queuing

Use this command to add a queuing class-map to a queuing policy map.

Default queuing class cannot be deleted.

Command Syntax

```
class type queuing default (q0|q1|q2|q3|q4|q5|q6|q7)
```

Parameters

NAME	Specify the class map name
<q0-q7>	Default queue name

Default

No default value is specified

Command Mode

Policy Map type queuing Mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)#
(config)#policy-map type queuing default default-out-policy
(config-pmap-que)#class type queuing default q0
```

clear qos statistics

Use this command to clear the quality of service (QoS) statistics.

Command Syntax

```
clear qos statistics (interface NAME |)(input | output |) (type (qos | queuing)|)
```

Parameters

NAME	Specify which interface to clear.

Default

By default, type QoS, type queuing class statistics on all interface's will be cleared, if no parameters configured

Command Mode

Privileged Exec mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
#clear qos statistics
#
```

clear interface counters

Use this command to clear all the interface counters.

Command Syntax

```
clear interface counters
```

Parameters

NA

Default

Command Mode

Privileged Exec mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
#clear interface counters
#
```

egress l2 exp encap map

Use this command to map a queue color to the some exp value for L2 traffic.

Use the no form of this command to remove the map.

Note: Color is an optional parameter. If not provided, the same map is set for all colors.

Command Syntax

```
l2 queue <0-7> (color (green|yellow|red)|) exp <0-7>
no l2 queue <0-7> (color (green|yellow|red)|)
```

Parameters

<0-7>	Identifying queue number
color	(green | yellow | red)
<0-7>	EXP value

Default

By default, queue values are one-to-one mapped to Exp. For example, queue 0 exp 0, queue 1 exp 1, and so on.

Command Mode

config-egress-exp-encap-map

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
(config)#qos profile exp-encap default (config-egress-exp-encap-map)#l2 queue
2 exp 1
(config-egress-exp-encap-map)#l2 queue 4 color yellow exp 3
```

Color is an optional parameter, so if users do not provide color for all colors, the same EXP is set. If users provide color, then only that specific color egress map is changed. If, however, users provide a map for all colors, as well as maps without color, the map with color will take priority.

For example,

```
(config-egress-exp-encap-map)#no l2 queue 1 color green
(config-egress-exp-encap-map)#no l2 queue 1
```

If a user wants to remove all the mapping of queue (for all colors), then there is no need to provide color, else the user can provide a specific color to remove a specific map.

egress l3 exp encap map

Use this command to map a DSCP value to the some EXP value.

For L3 traffic, use the no form of this command to remove the map.

Command Syntax

```
l3 dscp <0-63> exp <0-7>
no l3 dscp <0-63>
```

Parameters

<0-63>	DSCP value
<0-7>	EXP value

Default

By default, 8 DSCP values are mapped to one exp.

For example: DSCP 0-7 exp 0, DSCP 8-15 exp 1.

Command Mode

config-egress-exp-encap-map

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
(config)#qos profile exp-encap default
(config-egress-exp-encap-map)#l3 dscp 20 exp 1
(config-egress-exp-encap-map)#l3 dscp 40 exp 2
```

egress cos map

Use this command to map a queue value to the cos value.

Use the no form of this command to remove the map.

Note: Egress cos map will be taking effect only when remark cos is enabled.

Note: Color is an optional parameter. If not provided, the same map will be set for all colors.

Command Syntax

```
queue <0-7> (color (green|yellow|red)|) cos <0-7>
no queue <0-7> (color (green|yellow|red)|)
```

Parameters

<0-7>	Identifying queue number
color	(green|yellow|red)
<0-7>	CoS value

Default

By default, CoS to queue mapping is one to one.

Command Mode

config-egress-cos-map

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
(config)#qos profile queue-color-to-cos default
(config-egress-cos-map)#queue 1 color green cos 5
(config-egress-cos-map)#queue 1 cos 6
```

Color is an optional parameter. So if users do not provide color, for all colors same cos remarking will be set. If user provides color, then only for that specific color egress map will be changed. If user provides map for all colors as well as without color, map with color will take priority.

```
(config-egress-cos-map)#no queue 1 color green
(config-egress-cos-map)#no queue 1
```

If user want to remove all the mapping of queue (for all colors) no need to provide color, else can provide specific color to remove specific map.

egress dscp map

Use this command to map a queue to a dscp value.

Use the no form of this command to remove the map.

Note: Egress dscp map will be taking effect only when remark dscp is enabled.

Note: Color is an optional parameter. If not provided, the same map will be set for all colors.

Command Syntax

```
queue <0-7> (color (green|yellow|red)|) dscp <0-63>
no queue <0-7> (color (green|yellow|red)|)
```

Parameters

<0-7>	Identifying queue number
color	(green|yellow|red)
<0-63>	DSCP value

Default

By default, 8 DSCP values are mapped to one queue.

For example: DSCP 0-7 queue 0, DSCP 8-15 queue 1.

Command Mode

config-egress-dscp-map

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
(config)#qos profile dscp-to-dscp default
(config-egress-dscp-map)#dscp 20 color yellow dscp 40
(config-egress-dscp-map)#dscp 20 dscp 36
```

If user specifies color in map then map will be set for that specific color else for all colors same map will be set.

```
(config-egress-dscp-map)#no dscp 20 color yellow
(config-egress-dscp-map)#no dscp 20
```

If user want to remove all the mapping of dscp (for all colors) no need to provide color, else can provide specific color to remove specific map.

ingress cos map

Use this command to map a cos value to the queue.

Use the no form of this command to remove the map.

Note: Color mapping is fixed: DEI 0 will be mapped to color “green” and DEI 1 will be mapped to color “yellow.”

Command Syntax

```
cos <0-7> queue <0-7>
no cos <0-7>
```

Parameters

<0-7>	CoS value
<0-7>	Identifying queue number

Default

By default, CoS to queue mapping is one to one.

Command Mode

config-ingress-cos-map

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
(config)#qos profile cos-to-queue default
(config-ingress-cos-map)#cos 1 queue 2
```

ingress dscp map

Use this command to map a dscp value to the queue.

Use the no form of this command to remove the map.

Note: You can “remark” the dscp value for the incoming traffic at ingress via map by setting the last “dscp” field. You still need to match traffic with the incoming dscp value in the class-map even if you are remarking them at ingress via a dscp map. Traffic will be received with remarked dscp value at egress if no egress dscp map is applied. If an egress dscp map (such as dscp-to-dscp) is applied at the egress port, and dscp remarking is enabled, dscp will be remarked again according to the mapping given for the remarked dscp (the dscp value given in ingress dscp map).

Note: Last “dscp” parameter is remark_dscp value, which if provided will be set as the same ingress dscp value. Color is an optional parameter. If not provided, it will be set as the default value. Please refer the Configuration Guide for the default value table.

Command Syntax

```
dscp <0-63> queue <0-7> (color (green|yellow|red)|) (dscp <0-63>|)
no dscp <0-63>
```

Parameters

<0-63>	DSCP value
<0-7>	Identifying queue number
color	(green|yellow|red)

Default

By default, 8 DSCP values are mapped to one queue.

For example: DSCP 0-7 queue 0, DSCP 8-15 queue 1.

Command Mode

config-ingress-dscp-map

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
(config)#qos profile dscp-to-queue default
(config-ingress-dscp-map)#dscp 1 queue 2
```

ingress exp map

Use this command to map a exp value to the queue.

Use the no form of this command to remove the map.

Note: Color is an optional parameter. If not provided, color will be set to green.

Command Syntax

```
exp <0-7> queue <0-7> (color (green|yellow|red)|)
no exp <0-7>
```

Parameters

<0-7>	EXP value
<0-7>	Identifying queue number
color	(green|yellow|red)

Default

By default, EXP to queue mapping is one to one.

Command Mode

config-ingress-exp-queue-map

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
(config)#qos profile exp-to-queue default
(config-ingress-exp-queue-map)#exp 1 queue 4 color green
(config-ingress-exp-queue-map)#exp 2 queue 3
```

match access-group

Use this command to classify the group based on the access group.

Use the `no command` remove access group match criteria from a class map

Note: Match access-group is allowed only in “match-any” class type.

When match access-grp is configured, no more match criteria can be supported in the class-map.

When access-list is being used in class-map for match, only “permit rules” are allowed in the access-list.

Command Syntax

`match access-group` NAME

Parameters

NAME	Specify the access group name

Default

No default value is specified

Command Mode

Class-map mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)# class-map match-any class_acl
(config-cmap-qos)# match access-group my_acl
```

match cos

Use this command to classify the traffic based on cos

Use the `no command` to remove the match configuration.

Note: The match commands which accept range has silent exit which makes removal of these match configuration easier. For example, classify the traffic based on cos using the command `match cos 2,4,6` and remove the match configuration using the command `no match cos 2-6.`

Command Syntax

```
match cos WORD
no match cos (WORD|all)
```

Parameters

`WORD`	CoS value or list of specified CoS values. Valid values are from 0 to 7.
`all`	Delete all matched cos entries.

Default

No default value is specified

Command Mode

Class-map mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)#class-map type qos C_QOS1
(config-cmap-qos)#match cos 1
```

match cos inner

Use this command to classify the traffic based on inner cos.

Use the `no` command to remove the match configuration.

Note: The match commands which accept range has silent exit which makes removal of these match configuration easier. For example, classify the traffic based on inner cos using the command `match cos inner 2,4,6` and remove the match configuration using the command `no match cos inner 2-6`.

Command Syntax

```
match cos inner WORD
no match cos inner (WORD|all)
```

Parameters

`WORD`	Inner CoS value or list of specified CoS values. Valid values are from 0 to 7.
`all`	Delete all matched cos entries.

Default

No default value is specified

Command Mode

Class-map mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)#class-map type qos C_QOS1
(config-cmap-qos)#match cos inner 1
```

match dscp

Use this command to classify the traffic based on dscp.

Use the `no` command to remove the configured dscp value.

Note: The match commands which accept range has silent exit which makes removal of these match configuration easier. For example, classify the traffic based on dscp using the command `match dscp 2,4,6` and remove the match configuration using the command `no match dscp 2-6`.

Match dscp cannot be configured in the class-map where match precedence is already configured.

Command Syntax

```
match dscp [WORD | af11 | af12 | af13 | af21 | af22 | af23 | af31| af32 | af33 |
  af41 | af42 | af43 | cs1 | cs2 | cs3 | cs4 | cs5 | cs6| cs7 | default | ef]
```

```
no match dscp ([WORD | af11 | af12 | af13 | af21 | af22 | af23 | af31 | af32 | af33
  | af41 | af42 | af43 | cs1 | cs2 | cs3 | cs4  cs5 | cs6 | cs7 | default | ef]|all)
```

Parameters

`WORD`	<0-63> List of DSCP values.
`af11`	AF11 dscp (001010).
`af12`	AF12 dscp (001100)
`af13`	AF13 dscp (001110)
`af21`	AF21 dscp (010010)
`af22`	AF22 dscp (010100)
`af23`	AF23 dscp (010110)
`af31`	AF31 dscp (011010)
`af32`	AF32 dscp (011100)
`af33`	AF33 dscp (011110)
`af41`	AF41 dscp (100010)
`af42`	AF42 dscp (100100)
`af43`	AF43 dscp (100110)
`cs1`	CS1(precedence 1) dscp (001000)
`cs2`	CS2(precedence 2) dscp (010000)
`cs3`	CS3(precedence 3) dscp (011000)
`cs4`	CS4(precedence 4) dscp (100000)
`cs5`	CS5(precedence 5) dscp (101000)
`cs6`	CS6(precedence 6) dscp (110000)
`cs7`	CS7(precedence 7) dscp (111000)
`default`	Default dscp (000000)
`ef`	EF dscp (101110)
`all`	Delete all matched DSCP values.

Default

No default value is specified

Command Mode

Class-map mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)#class-map type qos C_QOS7
(config-cmap-qos)#match dscp 48
```

match ethertype

Use this command to classify the traffic based on the ethertype.

Use the no command to remove the match configuration.

Note: The match commands which accept range has silent exit which makes removal of these match configuration easier.

Qualifying the TPID values like 0x8100, 0x88A8, 0x9100 and 0x9200 etc as ethertype will not match if the traffic is flowing with the same TPId in the network.

Command Syntax

```
match ethertype WORD
no match ethertype(WORD|all)
```

Parameters

WORD	Enter ethertype <0x600 to 0xffff)> or list of ethertype separated by commas. For example, 0x806,0x8035 etc.
all	Delete all ethertype entries.

Default

No default value is specified

Command Mode

Class-map mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)#class-map type qos C_QOS1
(config-cmap-qos)#match ethertype 0x806
```

match ip rtp

Use this command to configure a class map to use the Real-Time Protocol (RTP) port as a match criteria.

Use the `no command` to remove the RTP port as a match criteria.

Note: The match commands which accept range has silent exit which makes removal of these match configuration easier. For example, classify the traffic based on RTP port using the command `match ip rtp 5000,7000,9000` and remove the match configuration using the command `no match ip rtp 5000-9000`.

Command Syntax

```
match ip rtp WORD
no match ip rtp (WORD|all)
```

Parameters

`WORD`	Specify User Datagram Protocol (UDP) or list of UDP ports that are using RTP. Valid values are from 2000 to 65535.
`all`	Delete all matched IP RTP values.

Default

No default value is specified

Command Mode

Class-map type qos

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)# class-map my_test
(config-cmap-qos)# match ip rtp 2300
```

match ipv6 dscp

Use this command to classify the ipv6 traffic based on DSCP.

Use the no command to remove the configured dscp value.

Note the following:

- The match commands which accept range have silent exit which makes removal of these match configuration easier. For example, classify the traffic based on dscp using the command `match dscp 2,4,6` and remove the match configuration using the command `no match dscp 2-6`.
- The `match ipv6 dscp` command cannot be configured in the class-map where match ipv6 precedence is already configured.
- Any `match ipv6` commands cannot be configured in the class-map where `match ipv4` commands are already configured.

Command Syntax

```
match ipv6 dscp [WORD | af11 | af12 | af13 | af21 | af22 | af23 | af31| af32 | af33
  | af41 | af42 | af43 | cs1 | cs2 | cs3 | cs4 | cs5 | cs6| cs7 | default | ef]
no match ipv6 dscp ([WORD | af11 | af12 | af13 | af21 | af22 | af23 | af31 | af32 |
  af33 | af41 | af42 | af43 | cs1 | cs2 | cs3 | cs4cs5 | cs6 | cs7 | default |
  ef]|all)
```

Parameters

`WORD`	<0-63> List of DSCP values.
`af11`	AF11 dscp (001010).
`af12`	AF12 dscp (001100)
`af13`	AF13 dscp (001110)
`af21`	AF21 dscp (010010)
`af22`	AF22 dscp (010100)
`af23`	AF23 dscp (010110)
`af31`	AF31 dscp (011010)
`af32`	AF32 dscp (011100)
`af33`	AF33 dscp (011110)
`af41`	AF41 dscp (100010)
`af42`	AF42 dscp (100100)
`af43`	AF43 dscp (100110)
`cs1`	CS1 (precedence 1) dscp (001000)
`cs2`	CS2 (precedence 2) dscp (010000)
`cs3`	CS3 precedence 3) dscp (011000)
`cs4`	CS4 (precedence 4) dscp (100000)
`cs5`	CS5 (precedence 5) dscp (101000)
`cs6`	CS6 (precedence 6) dscp (110000)
`cs7`	CS7 (precedence 7) dscp (111000)

`default`	Default dscp (000000)
`ef`	EF dscp (101110)
`all`	Delete all matched DSCP values

Default

No default value is specified

Command Mode

Class-map mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
(config)#class-map type qos C_QOS7
(config-cmap-qos)#match ipv6 dscp 48
```

match ipv6 layer4

Use this command to classify the IPv6 traffic based on layer4 protocol src/dest port value.

Use the no command to remove the match configuration.

Please note the following:

- The match commands which accept range have silent exit which makes removal of these match configuration easier. Only one type of layer 4 matching criteria is supported per class-map.
- Any `match ipv6` commands cannot be configured in the class-map where `match ipv4` commands are already configured.

Command Syntax

```
match ipv6 layer4 (tcp|udp|any) (source-port|destination-port) WORD
no match ipv6 layer4 (((tcp|udp|any) (source-port|destination-port) WORD) |all)
```

Parameters

`tcp`	Specify TCP protocol
`udp`	Specify UDP protocol
`any`	Specify ANY protocol - TCP/UDP
`source-port`	Specify source TCP/UDP port
`destination-port`	Specify destination TCP/UDP port
`WORD`	Enter TCP/UDP port value <1-65535> or range of values separated by commas such as 1 or 1,4-5 or 50,51,52
`all`	Delete all layer4 port entries

Default

No default value is specified

Command Mode

Class-map mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
(config)#class-map type qos C_QOS1
(config-cmap-qos)#match ipv6 layer4 tcp source-port 1
```

match ipv6 precedence

Use this command to IPv6 traffic classification based on precedence.

Use the no command to remove the match configuration.

Please note the following:

- The match commands which accept range has silent exit which makes removal of these match configuration easier. For example, classify the traffic based on precedence using the command match ipv6 precedence 2,4,6 and remove the match configuration using the command no match ipv6 precedence 2-6.
- The `match ipv6 precedence` command cannot be configured in the class-map where match ipv6 dscp is already configured.
- Any `match ipv6` commands cannot be configured in the class-map where `match ipv4` commands are already configured.

Command Syntax

```
match ipv6 precedence [WORD | critical | flash | flash-override | immediate |
  internet | network | priority | routine]
no match ipv6 precedence ([WORD | critical | flash | flash-override| immediate |
  internet | network | priority | routine]|all)
```

Parameters

`word`	IP precedence value
`critical`	Critical precedence
`flash`	Flash precedence
`flash-override`	Flash override precedence immediateImmediate precedence internetInternetwork control precedence networkNetwork control precedence
`priority`	Priority precedence
`routine`	Routine precedence
`all`	Delete all matched IP precedence values.

Default

No default value is specified

Command Mode

Class-map mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
(config)# class-map my_test
(config-cmap-qos)#match ipv6 precedence critical
```

match layer4

Use this command to classify the traffic based on layer4 protocol src/dest port value.

Use the no command to remove the match configuration.

Note: The match commands which accept range has silent exit which makes removal of these match configuration easier. Only one type of layer4 matching criteria is supported per class-map.

Command Syntax

```
match layer4 (tcp|udp|any) (source-port|destination-port) WORD
no match layer4 (((tcp|udp|any) (source-port|destination-port) WORD) |all)
```

Parameters

`tcp`	Specify TCP protocol
`udp`	Specify UDP protocol
`any`	Specify ANY protocol – TCP/UDP
`source-port`	Specify source TCP/UDP port
`destination-port`	Specify destination TCP/UDP port
`WORD`	Enter TCP/UDP port value <1-65535> or range of values separated by commas. e.g. 1 or 1,4-5 or 50,51,52
`all`	Delete all layer4 port entries

Default

No default value is specified

Command Mode

Class-map mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)#class-map type qos C_QOS1
(config-cmap-qos)#match layer4 tcp source-port 1
```

match mpls

Use this command to classify the traffic based on the top mpls exp value.

Use the no command to remove the match configuration.

Note: The match commands which accept range has silent exit which makes removal of these match configuration easier.

Command Syntax

```
match mpls experimental topmost WORD
no match mpls experimental topmost (WORD|all)
```

Parameters

WORD	Enter EXP value <0-7> or range of exp values seperated by commas. e.g. 2 or 2,4-5 or 3,4,5 or 2-4,5-7 etc.
all	Delete all exp values.

Default

No default value is specified

Command Mode

Class-map mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)#class-map type qos C_QOS1
(config-cmap-qos)# match mpls experimental topmost 3
```

match precedence

Use this command to traffic classification based on precedence.

Use the no command to remove the match configuration.

Note: The match commands which accept range has silent exit which makes removal of these match configuration easier. For example, classify the traffic based on precedence using the command `match precedence 2,4,6` and remove the match configuration using the command `no match precedence 2-6`.

Match precedence cannot be configured in the “match-all” class-map where match dscp is already configured.

Command Syntax

```
match precedence [WORD | critical | flash | flash-override | immediate | internet |
  network | priority | routine]
no match precedence ([WORD | critical | flash | flash-override| immediate |
  internet | network | priority | routine]|all)
```

Parameters

`word`	IP precedence value
`critical`	Critical precedence
`flash`	Flash precedence
`flash-override`	Flash override precedence
`immediate`	Immediate precedence
`internet`	Internetwork control precedence
`network`	Network control precedence
`priority`	Priority precedence
`routine`	Routine precedence
`all`	Delete all matched IP precedence values.

Default

No default value is specified

Command Mode

Class-map mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)# class-map my_test
(config-cmap-qos)#match precedence critical
```

match vlan

Use this command to classify the traffic based on a VLAN.

Use the `no` command to remove the match configuration.

Note: The match commands which accept range has silent exit which makes removal of these match configuration easier. For example, classify the traffic based on VLAN using the command `match vlan 2,4,6` and remove the match configuration using the command `no match vlan 2-6`.

Command Syntax

```
match vlan WORD
no match vlan (WORD|all)
```

Parameters

`WORD`	Enter VLAN ID <1-4094> or range of VLAN ID's separated by commas. For example, 2 or 2,4-5 or 50,51,52 or 100-120,122-130 etc.
`all`	Delete all VLAN ID entries.

Default

No default value is specified

Command Mode

Class-map mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)#class-map type qos C_QOS1
(config-cmap-qos)#match vlan 100
```

match vlan inner

Use this command to classify the traffic based on the inner VLAN.

Use the no command to remove the match configuration.

Note: The match commands which accept range has silent exit which makes removal of these match configuration easier. For example, classify the traffic based on the inner VLAN using the command `match vlan inner 2,4,6` and remove the match configuration using the command `no match vlan inner 2-6`.

Command Syntax

```
match vlan inner WORD
no match vlan inner (WORD|all)
```

Parameters

`WORD`	Enter VLAN ID <1-4094> or list of VLAN ID's separated by commas. For example, 2,4 etc.
`all`	Delete all VLAN ID entries.

Default

No default value is specified

Command Mode

Class-map mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)#class-map type qos C_QOS1
(config-cmap-qos)#match vlan inner 1
```

police

Use this command to configure policing of the data rates for a particular class of traffic.

Use the no command to remove a policing configuration.

Note: Committed Information Rate (CIR) and Excess Information Rate (EIR) can only be whole numbers.

The default burst is 5 ms traffic of the configured rate. Burst configured in milliseconds and microseconds are converted in kbytes by calculating it with input rates.

Police rate (cir/eir) value in percentage is only applicable on physical interfaces.

Command Syntax

For Qumran MX:

```
police (colour-blind | colour-aware|) (cir) (<1-720000000> (kbps|mbps|gbps) |
  percent <1-100>)((eir (<1-720000000> (kbps|mbps|gbps) | percent <1-100>)|)((bc)
  <1-4161> (kbytes|mbytes|ms|us)|)((be) <1-4161> (kbytes|mbytes|ms|us)|))
no police (colour-blind | colour-aware|) (cir) (<1-720000000> (kbps|mbps|gbps) |
  percent <1-100>)((eir (<1-720000000> (kbps|mbps|gbps) | percent <1-100>)|)((bc)
  <1-4161> (kbytes|mbytes|ms|us)|)((be) <1-4161> (kbytes|mbytes|ms|us)|))
```

For Qumran AX:

```
police (colour-blind | colour-aware|) (cir) (<1-500000000> (kbps|mbps|gbps) |
  percent <1-100>)((eir (<1-500000000> (kbps|mbps|gbps) | percent <1-100>)|)((bc)
  <1-4161> (kbytes|mbytes|ms|us)|)((be) <1-4161> (kbytes|mbytes|ms|us)|))
no police (colour-blind | colour-aware|) (cir) (<1-500000000> (kbps|mbps|gbps) |
  percent <1-100>)((eir (<1-500000000> (kbps|mbps|gbps) | percent <1-100>)|)((bc)
  <1-4161> (kbytes|mbytes|ms|us)|)((be) <1-4161> (kbytes|mbytes|ms|us)|))
```

Parameters

colour-blind	Do not police on color.
colour-aware	Do police on color.
cir	Committed information rate.
eir	Excess information rate.
kbps	Specify the units of kbps per second.
mbps	Specify the units of mbps per second.
gbps	Specify the units of gbps per second.
bc <1-4161>	Burst rate committed.
be <1-4161>	Burst rate extended.
ms	Specify the units of bc/be in milliseconds.
us	Specify the units of bc/be in microseconds.

Default

By default, policer type is colour-blind

Command Mode

Policy-map mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)# policy-map type qos 2345
(config-pmap-qos)#class type qos 2345
(config-pmap-c-qos)# police cir 2 mbps eir 4 mbps bc 2 mbytes be 4 mbytes
```

policy-map

Use this command to create a policy map and enter policy-map mode.

Use the no form of the command to remove a policy map.

Note: You cannot delete a policy map if it is attached to an interface.

Command Syntax

```
policy-map {NAME | (type (qos |queuing default) NAME)}
no policy-map {NAME | (type (qos |queuing default) NAME)}
```

Parameters

NAME	Policy map name (maximum 32 characters)
qos	QoS policy map
queuing	Queuing policy map

Default

No default value is specified

Command Mode

Configuration mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)#
(config)#policy-map type qos PQOS
```

priority level <0-7>

Use this command to configure a single output queuing class as the priority queue.

Use no command to unset the priority level from the queue.

Strict priority mode supports 8 level, i.e., 0 to 7. The queue is constructed such that a higher priority level has a higher priority.

If more than one queue is in the same level, then there will be fair queuing between those queues.

On qos-enable, all the queues will be in strict-priority. After changing the mode or un-setting the priority, queues will be set for WFQ mode with the default weight 1. To set them again in strict priority, the user needs to configure them manually.

Command Syntax

```
priority level <0-7>
no priority level
```

Parameters

<0-7>	Priority level

Default

No default value is specified

Command Mode

Policy map-class type queuing mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
#configure terminal
(config)#policy-map type queuing default default-out-policy
(config-pmap-que)#class type queuing default q0
(config-pmap-c-que)#priority level 2
```

priority (QoS)

Use this command to set the user priority for the class attached to this policy-map

Use the no parameter with this command to unset the priority value

Note: The higher the priority number, higher the priority for the class in a policy-map.

User configured priority takes effect over default priority.

Command Syntax

```
priority <1-1000>
no priority
```

Parameters

<1-1000>	Priority value

Default

No default value is specified

Command Mode

Policy-class-map mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
#configure terminal
(config)#policy-map pmap1
(config-pmap)#class cmap1
(config-pmap-c)#priority 20
```

qos (enable | disable)

Use this command to globally enable or disable Quality-of-Service (QoS).

Note: Enabling or disabling QoS is a disruptive operation, stopping all traffic on ports which causes traffic loss.

Command Syntax

```
qos (enable | disable)
```

Parameters

None

Default

By default, QoS is disabled

Command Mode

Configure

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
#configure terminal
(config)# qos enable

(config)#qos disable
```

qos map-profile

Use this command to attach (map) a profile to an interface.

Use the no form of this command to remove a profile.

Note: By-default, “default” profiles are attached on their supported interfaces (cos-to-queue and queue-to-cos on L2 interfaces and dscp-to-queue and dscp-to-dscp on L3 interfaces).

You can create and attach your own profile to supported interfaces. After removing a user-defined profiles from an interface, the “default” profile is applied.

Command Syntax

```
qos map-profile (cos-to-queue | dscp-to-queue | queue-color-to-cos | dscp-to-dscp |
  exp-encap) NAME
no qos map-profile (cos-to-queue | dscp-to-queue | queue-color-to-cos | dscp-to-
  dscp | exp-encap) NAME
```

Parameters

cos-to-queue	Profile for cos to queue map
dscp-to-queue	Profile for dscp to queue map
queue-color-to-cos	Profile for queue color to cos map
dscp-to-dscp	Profile for inDscp to outDscp map
exp-encap	Profile for EXP encapsulation map
exp-to-queue	Profile for EXP to queue map
NAME	Profile map name (maximum 32 characters)

Default

By default, the default cos-to-queue-profile is applied to an L2 interface, and the default dscp-to-queue profile is attached to an L3 interface.

Command Mode

Interface modes

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
(config-if)#qos map-profile cos-to-queue cos-map
(config-if)#qos map-profile dscp-to-queue dscp-map
(config-if)#qos map-profile queue-color-to-cos egress-cos-map
(config-if)#qos map-profile dscp-to-dscp dscp-dscp-map
(config-if)#qos map-profile exp-encap exp-encap-map
```

qos profile

Use this command to create new profiles or to update “default” profiles.

Use the no form of this command to remove the profiles.

Note: “default” profiles can only be updated and not be deleted. User can create/delete user-defined profiles.

Only “default” exp-to-queue profile is supported.

Note: “exp-encap” profile will be ineffective on tunnels with only 2 nodes with PHP configuration.

Command Syntax

```
qos profile (cos-to-queue | dscp-to-queue | queue-color-to-cos | dscp-to-dscp |
  exp-encap)(NAME|default)
no qos profile (cos-to-queue | dscp-to-queue | queue-color-to-cos | dscp-to-dscp |
  exp-encap)NAME
qos profile exp-to-queue default
```

Parameters

`cos-to-queue`	Profile for cos to queue map
`dscp-to-queue`	Profile for dscp to queue map
`queue-color-to-cos`	Profile for queue color to cos map
`dscp-to-dscp`	Profile for inDscp to outDscp map
`exp-encap`	Profile for the exp encapsulation map
`exp-to-queue`	Profile for exp to queue map
`NAME`	Profile map name (maximum 32 characters)

Default

By default, “default” profile is created for all the profile types. These profiles can only be updated by the user neither be created nor be destroyed.

Command Mode

Configure modes

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

To create a new profile:

```
(config)#qos profile cos-to-queue cos-map
(config)#qos profile dscp-to-queue dscp-map
(config)#qos profile queue-color-to-cos egress-cos-map
(config)#qos profile dscp-to-dscp dscp-dscp-map
(config)#qos profile exp-encap exp-encap-map
```

To update the “default” profile:

```
(config)#qos profile cos-to-queue default
(config)#qos profile dscp-to-queue default
(config)#qos profile queue-color-to-cos default
(config)#qos profile dscp-to-dscp default
(config)#qos profile exp-encap default
(config)#qos profile exp-to-queue default
```

qos red-drop-disable

Use this command to disable red packet drop in the system. Red packets are dropped in the system by default to achieve ingress rate limiting via policer and storm control. However, this command is used when there is no use-case for rate limiting traffic and red packets need to be allowed in the system

Use the no form of this command to enable red packet drop.

Command Syntax

```
qos red-drop-disbale
no qos red-drop-disable
```

Parameters

None

Defaults

By default, red packet drop is enabled.

Command Mode

Configure

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
#configure terminal
(config)# qos red-drop-disable
(config)#no qos red-drop-disable
```

qos remark

Use this command to enable remarking of the Class of service (CoS) and Differentiated Services Control Protocol (DSCP) set by the egress map.

Use the no command to disable remarking of the CoS and DSCP.

Command Syntax

In Config mode :

```
qos remark (cos|dscp)
no qos remark (cos|dscp)
```

In interface mode:

```
qos remark (cos|dscp)(enable|disable)
no qos remark (cos|dscp)
```

Parameters

`type`	Remarking type, e.g. CoS or DSCP
`(enable|disable)`	Remarking action

Default

By default, remarking is disabled.

Command Mode

Configure Mode

Interface Mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)#qos remark cos
(config)#qos remark dscp
(config-if)# qos remark cos disable
(config-if)# qos remark cos enable
(config-if)# qos remark dscp disable
```

Interface remarking will take priority over global remarking configurations.

qos statistics

Use this command to enable Quality of Service (QoS) statistics.

Use the no command to disable QoS statistics

Note: Class-map statistics is cleared whenever the match or action property of the class is modified dynamically.

Command Syntax

```
qos statistics
no qos statistics
```

Parameters

None

Default

By default, QoS statistics is disabled

Command Mode

Configure Mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)#qos statistics
(config)#
```

qos untagged-priority

Use this command to set internal priority for untagged traffic on L2 ports.

Use the no form of the command to remove the configuration.

Note: This command is applicable only on L2 ports.

Command Syntax

```
qos untagged-priority <0-7>
no qos untagged-priority
```

Parameters

qos	Quality of Service
untagged-priority	Internal priority for untagged traffic
<0-7>	Value

Default

No default value is specified

Command Mode

Interface mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)#interface xe1
(config-if)#qos untagged-priority 3
```

queue-limit

Use this command to configure tail drop by setting queue limits on egress queues.

Use the `no command` to remove a queue limit.

Command Syntax

```
queue-limit (<1-629145600>) (packets|bytes|kbytes|mbytes|ms)
no queue-limit
```

Parameters

`<1-629145600>`	Specify queue-limit in packets, bytes, or Kilobytes.
	Max value for bytes is min 1024, max 629145600
	Max value for kilobytes is 614400
	Max value for megabytes is 600, Max value for packets is 614400
`packets`	Specify the units of queue-limit in packets
`bytes`	Specify the units of queue-limit in bytes
`kbytes`	Specify the units of queue-limit in kilobytes
`mbytes`	Specify the units of queue-limit in mega-bytes
`ms`	Specify the units of queue-limit in milliseconds

Default

Default queue size is 62914560 bytes

Command Mode

Policy-class-map-queue mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)# policy-map type queuing default P1
(config-pmap-que)#class type queuing default q1
(config-pmap-c-que)# queue-limit 1 mbytes
```

random-detect

Use this command to configure weighted random early detection (WRED).

Use the no command to remove a WRED configuration.

Command Syntax

```
random-detect (green (minimum-threshold|)< 1-629145600>
  (bytes|kbytes|mbytes|ms|packets)(maximum-threshold|) <1-629145600>
  (bytes|kbytes|mbytes|ms|packets) (drop-probability <1-100>|) yellow (minimum-
  threshold|) < 1-629145600> (bytes|kbytes|mbytes|ms|packets)(maximum-threshold|) <
  1-629145600> (bytes|kbytes|mbytes|ms|packets)(drop-probability <1-100>|)(weight
  <1-31>|))
no random-detect
```

Parameters

minimum-threshold	
	Specify the minimum threshold. In the range of <1-629145600>
maximum-threshold	
	Specify the maximum threshold. In the range of <1-629145600>
packets	Specify the units of queue-limit in packets – range (min 1, max 614400)
bytes	Specify the units of threshold in bytes – range (min 1024, max 629145600)
kbytes	Specify the units of threshold in kilobytes – range (min 1, max 614400)
mbytes	Specify the units of threshold in mega-bytes – range (min 1, max 600)
ms	Specify the units of threshold in milliseconds – range (min 1, max 50)
	Threshold value in ms will be calculated from interface-speed and will be converted into bytes
drop-probability	
	Drop-probability is the fraction of packets dropped when the average queue depth is at the maximum threshold.It can be configured per color Specify the drop-probability in the range <1-100>
weight	Configures the weight factor used in calculating the average queue length. Specify the weight in the range <1-31>. Value specified will be set for all colors

Default

No default value is specified

Command Mode

Policy-class map queue mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)# policy-map type queuing default P1
```

```
(config-pmap-que)#class type queuing q1
(config-pmap-c-que)# random-detect minimum-threshold 1000 mbytes maximum-
threshold 2000 mbytes
```

queue shaper

Use this command to configure shaping on an egress queue to impose a maximum rate on it.

Use the `no command` to remove a shaping configuration.

Note: Minimum configurable queueing shape rate is 469 Kbps and maximum queuing shape rate is 483 Gbps. Granularity is 469 Kbps for low range and 1.56 % for higher range.

Command Syntax

```
queue shaper (<1-483000000>(kbps|mbps|gbps) | percent <1-100>)
no queue shaper (<1-483000000> (kbps|mbps|gbps) | percent <1-100>)
```

Parameters

`<1-483000000>`	Shaping is based on an average rate. Average rate for shaping in the range of `<1-483000000>.Min shape rate configured is 469 kbps and max shape rate configured is 483 gbps.`
`kbps`	Specify the units of kbps per second
`mbps`	Specify the units of mbps per second
`gbps`	Specify the units of gbps per second
`percent`	Specify the percentage from 1 to 100

Default

No default value is specified

Command Mode

Policy-class-map queue mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)# policy-map type queuing default default-out-policy
(config-pmap-que)# class type queuing default q0
(config-pmap-c-que)# queue shaper percent 25
(config-pmap-c-que)#
```

port shaper

Use this command to configure shaping on an egress port to impose a maximum rate on it.

Use the no form of the command to remove a shaping configuration.

Note: Minimum configurable port shape rate is 52 Kbps with Granularity of 52 Kbps and maximum shape rate is 1000 Gbps, but applicable maximum rate may be speed of interface.

Command Syntax

```
port shaper rate <1-1000000000> (kbps|mbps|gbps)
no port shaper rate
```

Parameters

`<1-1000000000>`	Specify rate for shaping in the range of `<1-1000000000>. Min shape rate configured on port is 52kbps and max shape rate configured on port is 1000gbps`
`kbps`	Specify the units of kbps per second.
`mbps`	Specify the units of mbps per second.
`gbps`	Specify the units of gbps per second.

Default

No default value is specified

Command Mode

Interface mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)# interface xe11
(config-if)# port shaper rate 100 mbps
```

service-policy type qos

Use this command to attach a service-policy of type qos to the interface.

Use the `no` command to remove a service-policy from an interface.

Command Syntax

```
service-policy type qos input NAME
no service-policy type qos input NAME
```

Parameters

`type`	Specify whether the policy map is of type qos.
`NAME`	Specify the policy map to attach to this interface.

Default

No default value is specified

Command Mode

Interface mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)#int xe3
(config-if)#service-policy type qos input PQOS
```

service-policy type queuing

Use this command to attach a service-policy of type queuing to the interface.

Use the no command to remove a service-policy from an interface.

Command Syntax

```
service-policy type queuing output NAME
no service-policy type queuing output NAME
```

Parameters

type	Specify whether the policy map is of type queuing.
NAME	Specify the policy map to attach to this interface.

Default

By default, default-out-policy is attached on all interface

Command Mode

Interface mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)#int xe3
(config-if)#service-policy type queuing output PQOS
```

set cos

Use this command for matching traffic classes set action as change cos in the egress packet to the prescribed value.

Use the `no command` to remove the assigned value from the class.

Note: This command only applies to normal switch ports of type trunk/hybrid. This command does not apply to AC, CEP, or PNP ports. See the qos map-profile command for options for these types of ports.

Command Syntax

```
set cos <0-7>
no set cos <0-7>
```

Parameters

`<0-7>`	CoS value to assign for this class of traffic

Default

No default value is specified

Command Mode

Policy-map-class-qos mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)#policy-map my_policy1
(config-pmap-qos)#class traffic_class2
(config-pmap-c-qos)#no set cos 3
(config-pmap-c-qos)#
```

set dscp

Use this command for matching traffic classes set action as change DSCP in the egress packet to the prescribed value.

Use the no command to remove the assigned value from the class

Command Syntax

```
set dscp (<0-63>|af11| af12| af13| af21| af22| af23| af31| af32| af33| af41| af42|
  af43| cs1| cs2| cs3| cs4| cs5| cs6| cs7| default| ef )
no set dscp (<0-63>|af11| af12| af13| af21| af22| af23| af31| af32| af33| af41|
  af42| af43| cs1| cs2| cs3| cs4| cs5| cs6| cs7| default| ef )
```

Parameters

<0-63>	DSCP value
af11	DSCP (001011) decimal value 11
af12	DSCP (001100) decimal value 12
af13	DSCP (001101) decimal value 13
af21	DSCP (010101) decimal value 21
af22	DSCP (010110) decimal value 22
af23	DSCP (010111) decimal value 23
af31	DSCP (011111) decimal value 31
af32	DSCP (010000) decimal value 32
af33	DSCP (010001) decimal value 33
af41	DSCP (101001) decimal value 41
af42	DSCP (101010) decimal value 42
af43	DSCP (101011) decimal value 38
cs1	(Precedence 1) DSCP (001000) decimal value 8
cs2	(Precedence 2) DSCP (010000) decimal value 16
cs3	(Precedence 3) DSCP (011000) ecimal value 24
cs4	(Precedence 4) DSCP (100000) decimal value 32
cs5	(Precedence 5) DSCP (101000) decimal value 40
cs6	(Precedence 6) DSCP (110000) decimal value 48
cs7	(Precedence 7) DSCP (111000) decimal value 56
default	DSCP (000000) decimal value 0
ef	DSCP (101110) decimal value 46

Default

No default value is specified

Command Mode

Policy-map-class qos mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
#configure terminal
(config)#policy-map pmap1
(config-pmap)#class cmap1
(config-pmap-c)#set dscp af12
```

set precedence

Use this command for matching traffic classes set action as change precedence in the egress packet to the prescribed value.

Use the `no command` to leave the precedence value unchanged for the class

Command Syntax

```
set (precedence (<0-7>| critical| flash | flash-override|immediate|internet|
  network| priority| routine))
no set (precedence (<0-7>| critical| flash | flash-override|immediate|internet|
  network| priority| routine))
```

Parameters

`<0-7>`	Specify IP precedence value to assign for this class of traffic
`critical`	Critical precedence
`flash`	Flash precedence
`flash-override`	Flash override precedence
`immediate`	Immediate precedence
`internet`	Internetwork control precedence
`network`	Network control precedence
`priority`	Priority precedence
`routine`	Routine precedence

Default

No default value is specified

Command Mode

Policy-map-class qos mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)# policy-map policy1
(config-pmap-qos)# class class2
(config-pmap-c-qos)# set precedence 3
(config-pmap-c-qos)#
```

set queue

Use this command for matching traffic classes set action as change cos in the egress packet to the prescribed value.

Use the `no command` to remove the assigned value from the class.

Command Syntax

```
set queue <0-7>
no set queue <0-7>
```

Parameters

`<0-7>`	Specify queue value to assign for this class of traffic

Default

No default value is specified

Command Mode

Policy-map-class qos mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)# policy-map my_policy1
(config-pmap-qos)# class traffic_class2
(config-pmap-c-qos)# set queue 3
(config-pmap-c-qos)#
```

show class-map

Use this command to display qos/queuing class maps.

Command Syntax

```
show class-map (type (qos|queuing)|) (NAME|)
```

Parameters

NAME	Specify the named class map

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
#show class-map c1
  Type qos class-maps
  ===================
      class-map c1
         match cos 3
```

show interface counters

Use this command to see the interface counters.

Command Syntax

```
show interface IFNAME counters queue-stats
```

Parameters

IFNAME	Interface name.

Command Mode

Exec

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
#show interface xe1 counters queue-stats
E - Egress, I - Ingress, Q-Size is in bytes
+---+------+--------+---------+---------+-----------+
| Q | Q-Sz | Tx pkt | Tx byte | Drp pkt | Drop byte |
+---+------+--------+---------+---------+-----------+
q0   629160 100      12000     0         0
q1   629160 0        0         0         0
q2   629160 0        0         0         0
q3   629160 0        0         0         0
q4   629160 0        0         0         0
q5   629160 0        0         0         0
q6   629160 0        0         0         0
q7   629160 0        0         0         0
```

show policy-map

Use this command to display:

1. Type qos/queuing policy-map
2. Non zero statistics for type qos or queuing classes on interfaces

Command Syntax

```
show policy-map (NAME | statistics (type (qos|queuing(default|))|))
show policy-map (type (qos|queuing)|)
show policy-map interface NAME (statistics (type (qos|queuing)|))
```

Parameters

`qos`	Type qos policy-map
`statistics`	Displays QoS statistics.
`queuing`	Type queuing policy-maps
`default`	Default queue of the port
`Interface`	Interface on which to get policy-map statistics

Command Mode

Exec and Configure mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

Examples

```
#show policy-map A

```

show policy-map interface

Use this command to:

1. Display non zero QoS statistics and configurations of type QOS and queuing policy-maps on an interface
2. Display the interfaces and policy-maps attached on them

Note: Queuing policy map drop statistics include all drop packets count in the queue (even policer drops).

Note: In order to check statistics, QoS statistics profile needs to be enabled for Qumran devices. QoS can either use ingress-acl statistics profile or ingress-qos statistics profile. When ACL groups are configured on the same interface as QoS and both ACL and QoS need explicit counters, then ingress-qos statistics profile needs to be configured along with ingress-acl statistics profile. However, this will have other limitations on statistics profiles. Please refer hardware-profile statistics for more details.

Command Syntax

```
show policy-map interface (NAME (type (qos (input | output |)| queuing)|)|brief)
```

Parameters

NAME	Interface name.
type	QoS or queuing type
brief	brief policy interface.

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
#show policy-map interface xe1

Interface xe1
Type QoS statistics status : enabled

Service-policy (qos) input: A
-----------------------------
Class-map (qos): A (match all)
 match vlan 2
 set cos 3
      matched      : 88091758 packets, 132137620500 bytes
      transmitted  : 88091758 packets, 132137620500 bytes

Class-map (qos): B (match all)
 match vlan 3

Service-policy (queuing) output: default-out-policy
---------------------------------
Class-map (queuing): q0
  priority level 0
```

```
Class-map (queuing): q1
  priority level 1

Class-map (queuing): q2
  priority level 2

 ce50                      default-out-policy
```

show qos-profile

Use this command to show the all configured QoS profiles configurations like type, name, maps configured except for the default maps, attached info (to how many interfaces it is attached) etc,

Command Syntax

```
show qos-profile (type (cos-to-queue | dscp-to-queue | queue-color-to-cos | dscp-
  to-dscp | dscp-to-exp)|)(NAME|)
```

Parameters

cos-to-queue	Profile for cos to queue map
dscp-to-queue	Profile for dscp to queue map
queue-color-to-cos	Profile for queue color to cos map
dscp-to-dscp	Profile for inDscp to outDscp map
dscp-to-exp	Profile for dscp to exp map
exp-to-queue	Profile for exp to queue map
NAME	Profile map name (maximum 32 characters)

Command Mode

Exec, config, interface, class-map, policy-map and policy-map-class

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
#show policy-map interface xe1

Interface xe1
Type QoS statistics status : enabled

Service-policy (qos) input: A
----------------------------
Class-map (qos): A (match all)
 match vlan 2
 set cos 3
      matched      : 88091758 packets, 132137620500 bytes
      transmitted  : 88091758 packets, 132137620500 bytes

Class-map (qos): B (match all)
 match vlan 3

Service-policy (queuing) output: default-out-policy
-----------------------------------
Class-map (queuing): q0
  priority level 0
```

```

 ce50                      default-out-policy
```

show qos-profile interface

Use this command to show the all configured QoS profiles configurations attached on an interface.

Command Syntax

```
show qos-profile interface NAME
```

Parameters

NAME	Profile map name (maximum 32 characters)

Command Mode

Exec, config, interface, class-map, policy-map and policy-map-class

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)#show qos-profile interface xe11
 profile name: cos-map
 profile type: cos-to-queue
 mapping:
 qos profile cos-to-queue cos-map
 cos 0 dei 0 queue 0 color green
 cos 0 dei 1 queue 0 color yellow
 cos 0 queue 0
 cos 1 dei 0 queue 1 color green
 cos 1 dei 1 queue 1 color yellow
 cos 1 queue 1
 cos 2 dei 0 queue 2 color green
 cos 2 dei 1 queue 2 color yellow
 cos 2 queue 2
 cos 3 dei 0 queue 3 color green
 cos 3 dei 1 queue 3 color yellow
 cos 3 queue 3
 cos 4 dei 0 queue 4 color green
 cos 4 dei 1 queue 4 color yellow
 cos 4 queue 4
 cos 5 dei 0 queue 5 color green
 cos 5 dei 1 queue 5 color yellow
 cos 5 queue 5
 cos 6 dei 0 queue 6 color green
```

show queuing interface

Use this command to see the configurations of queues that are attached to an interface.

Command Syntax

```
show queuing interface NAME
```

Parameters

NAME	Interface name.

Command Mode

Exec & config mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
# show queuing interface xe1/1
Egress Queuing for Ethernet xe1/1 [System]
------------------------------------------------------------------------------
----------------------
L0              L1              L2              Group PrioLevel   Shape
Bandwidth
------------------------------------------------------------------------------
----------------------
q0                                                      -      High        -
-
q1                                                      -      High        -
-
q2                                                      -      High        -
-
q3                                                      -      High        -
-
q4                                                      -      High        -
-
q5                                                      -      High        -
-
q6                                                      -      High        -
-
q7                                                      -      High        -
-
```

show running-config qos

Use this command to show the user configured QoS configurations.

Command Syntax

```
show running-config qos (all|)
```

Parameters

`all`	Show all QoS related configuration information including all defaults.

Command Mode

Exec, config, interface, class-map, policy-map and policy-map-class

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
#show running-config qos
qos enable
!
!
#show running-config qos  ?
  all  diplay all qos info including defaults
  |    Output modifiers
  >    Output redirection
  <cr>

#show running-config qos  all
qos enable
!
qos profile cos-to-queue default
 cos 0 dei 0 queue 0 color green
 cos 0 dei 1 queue 0 color yellow
 cos 0 queue 0
 cos 1 dei 0 queue 1 color green
 cos 1 dei 1 queue 1 color yellow
 cos 1 queue 1
 cos 2 dei 0 queue 2 color green
 cos 2 dei 1 queue 2 color yellow
 cos 2 queue 2
 cos 3 dei 0 queue 3 color green
 cos 3 dei 1 queue 3 color yellow
 cos 3 queue 3
 cos 4 dei 0 queue 4 color green
 cos 4 dei 1 queue 4 color yellow
 cos 4 queue 4
 cos 5 dei 0 queue 5 color green

storm-control

Use this command to set the rising threshold level for broadcast, multicast, or destination lookup failure traffic. The storm control action occurs when traffic utilization reaches this level.

Storm control is used to block the forwarding of unnecessary flooded traffic. A packet storm occurs when a large number of broadcast packets are received on a port. Forwarding these packets can cause the network to slow down or time out.

The minimum granularity for storm-control is 64kbps.

Use the no form of this command to disable storm control.

Command Syntax

```
storm-control (broadcast|multicast|dlf) (level LEVEL | <0-1000000000>
  (kbps|mbps|gbps))
no storm-control (broadcast|multicast|dlf)
```

Parameters

broadcast	Broadcast rate limiting.
multicast	Multicast rate limiting.
dlf	Destination lookup failure limiting.
level	Sets the percentage of the threshold.
LEVEL	The percentage of the threshold; percentage of the maximum speed (pps) of the interface <0.0000-1000.0000>.
<0-1000000000>	Sets absolute threshold value <0-1000000000>
kbps	specifies the units of Kilobits per second.
mbps	specifies the units of Megabits per second.
gbps	specifies the units of Gigabits per second.

Default

By default, storm control is disabled

Command Mode

Interface mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
#configure terminal
(config)#interface xe1
(config-if)#storm-control broadcast level 30

(config)#interface xe2
(config-if)#storm-control multicast level 30
```

```
(config)#interface xe3
(config-if)#storm-control multicast 300 mbps

(config)#interface xe4
(config-if)#no storm-control multicast
```

tust dscp

Use this command to classify the traffic based on dscp map on L2 port.

Use the no form of the command to remove the configuration.

Note: By default, the trust of L2 ports is CoS. If the user wants to map the traffic according to the DSCP value, `trust dscp` can be set on ports to achieve the requirement.

Tagged packet color is based on the DEI bit. Untagged packet color is based on DSCP value.

Out-DSCP option in dscp-to-queue profile is not applicable on L2 interfaces when trust DSCP is set

Only “default” dscp-to-queue profile is valid for trust DSCP. User-defined `dscp-to-queue` cannot be attached on L2 interfaces.

Command Syntax

```
trust dscp
no trust dscp
```

Parameters

`trust`	Configure port trust state
`dscp`	Classifies ingress packets with the packet DSCP values

Default

No default value is specified

Command Mode

Interface mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)#interface xe1
(config-if)#trust dscp
```

wfq-queue weight

Use this command to set WFQ-queue weight for a queue.

Use the no form of the command to un-set configured WFQ configuration.

Command Syntax

```
wfq-queue weight <1-127>
no wfq-queue weights
```

Parameters

<1-127>	WFQ queue weight to be configured.

Default

No default value is specified

Command Mode

Policy-class-map queuing Mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Examples

```
(config)#policy-map type queuing default default-out-policy
(config-pmap-que-def)# class type queuing default q0
(config-pmap-c-que-def)#wfq-queue weight 2
```

vc-qos map-profile

Use this command is used to binding PCP to TC mapping profile to attachment circuits.

Use the no form of this command to remove the profile.

Note: Profile configured on the VPLS service is effective for all attachment circuits associated with VPLS service. However, if a profile is bound to attachment circuit, that profile takes higher priority for that attachment circuit.

Command Syntax

```
vc-qos map-profile (cos-to-queue | queue-color-to-cos) NAME
no vc-qos map-profile (cos-to-queue | queue-color-to-cos)  NAME
```

Parameters

cos-to-queue	Profile for cos to queue map
queue-color-to-cos	Profile for queue-color to cos map
NAME	Profile map name (maximum 32 characters)

Default

By-default, “default” global cos-to-queue map is applied on an attachment-circuit if no user-defined cos-to-queue profile is applied on interface or vpls-service.

Traffic received on VPLS service will be affected by QoS treatment by configurations in the following order:

1. PCP to TC/TC to PCP profile configuration bound to attachment circuit.
2. PCP to TC/TC to PCP profile configuration bound to VPLS service.
3. PCP to TC/TC to PCP profile configuration bound to ingress port.
4. Global PCP to TC/TC to PCP profile configuration.

Command Mode

interface-vpls modes

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
(config)#interface xe1
(config-if)#switchport
(config-if)#mpls-vpls vpls1 service-template st1
(config-if-vpls)#vc-qos map-profile queue-color-to-cos qc-profile-2
```

vpls-qos map-profile

Use this command is used to binding PCP to TC mapping profile to VPLS service.

Use the no form of this command to remove the profile.

Command Syntax

```
vpls-qos map-profile (cos-to-queue | queue-color-to-cos) NAME
no vpls-qos map-profile (cos-to-queue | queue-color-to-cos) NAME
```

Parameters

`cos-to-queue`	Profile for cos to queue map
`queue-color-to-cos`	Profile for queue-color to cos map
`NAME`	Profile map name (maximum 32 characters)

Default

By-default, “default” global `cos-to-queue` map is applied on a VPLS service if no user-defined `cos-to-queue` profile is applied on interface.

Traffic received on a VPLS service will be affected by QoS treatment by configurations in the following order:

1. PCP to TC profile configuration bound to VPLS service.
2. PCP to TC profile configuration bound to ingress port.
3. Global PCP to TC profile configuration.

Command Mode

vpls modes

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
(config)#mpls vpls vpls1 1
(config-vpls)#vpls-qos map-profile cos-to-queue cq-profile-1
```

SECTION 16 Virtual eXtensible Local Area Network

Virtual eXtensible Local Area Network Configuration Guide

Contents

This guide contains the chapters:

CHAPTER 1 Overview

This chapter provides an overview of Virtual eXtensible Local Area Network (VXLAN) and its implementation with OcNOS. VXLAN creates LAN segments using a MAC in IP encapsulation. The encapsulation carries the original L2 frame received from a host to the destination in another server using IP tunnels. The endpoints of the virtualized tunnel formed using VXLAN are called VTEPs (VXLAN Tunnel EndPoints). This technology allows the network to support several tenants with minimum changes in the network. The VTEPs carry tenant data in L3 tunnels over the network. The tenant data is not used in routing or switching. This aids in tenant machine movement and allows the tenants to have the same IP or MAC addresses on end devices, hosts/VM's.

OcNOS supports VxLAN IPv4 tunnels, but both IPv4 and IPv6 hosts are supported.

Terminology

Terms related to VXLAN configuration are defined in the table below.

IGMP	Internet Group Management Protocol
PIM	Protocol Independent Multicast
VLAN	Virtual Local Area Network
VM	Virtual Machine
VNI	VXLAN Network Identifier (or VXLAN Segment ID)
VTEP	VXLAN Tunnel End Point. An entity that originates and/or terminates VXLAN tunnels
VXLAN	Virtual eXtensible Local Area Network
VXLAN Segment	VXLAN Layer 2 overlay network over which VMs communicate
VXLAN Gateway	An entity that forwards traffic between VXLANs

VXLAN Architecture

VXLAN runs over the existing networking infrastructure. It provides a means to "stretch" a Layer 2 network. In short, VXLAN is a Layer 2 overlay scheme on a Layer 3 network.

Each overlay is termed as a VXLAN segment. Only VMs within the same VXLAN segment can communicate with each other. Each VXLAN segment is identified through a 24-bit segment ID termed the "VXLAN Network Identifier (VNI)". This allows up to 16 million VXLAN segments to coexist within the same administrative domain.

VNI identifies the scope of the inner MAC frame originated by the individual VM. Hence, we can have overlapping MAC addresses across segments but never have traffic "cross over" since the traffic is isolated using the VNI. The VNI is in an outer header that encapsulates the inner MAC frame originated by the VM.

Any packets (including ARP-ND) that are uplifted to the VxLAN CPU queue from any port are rate limited to 500 packets/second. This is done to protect the system and CPU during an ARP storm.

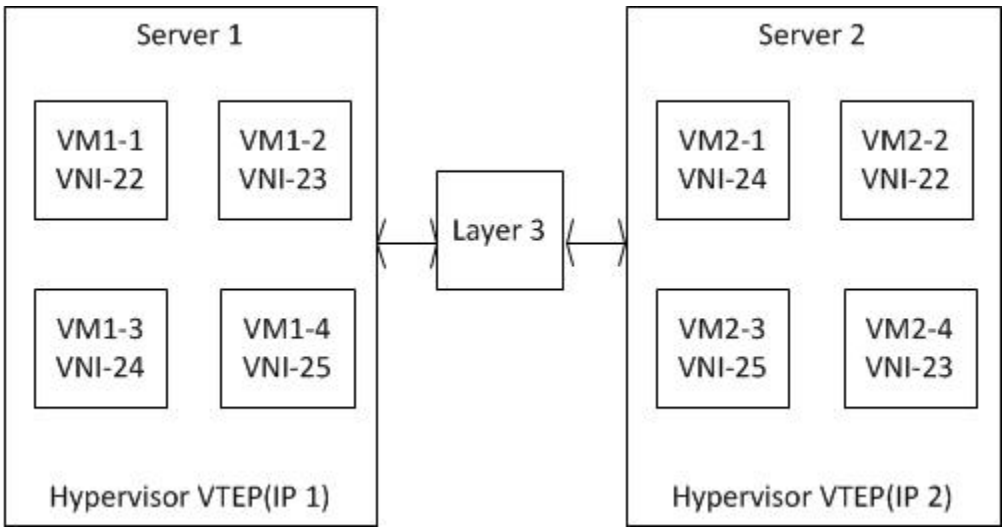

Figure 1-125: VXLAN Deployment - VTEPs across a Layer 3 Network

CHAPTER 2 VXLAN-EVPN Configuration

This section contains basic VXLAN-EVPN configuration examples.

VXLAN (Virtual eXtended LAN) creates LAN segments using a MAC-in-IP encapsulation. The encapsulation carries the original L2 frame received from a host to the destination in another host using IP tunnels. The endpoints of the virtualized tunnel formed using VXLAN are called VTEPs (VXLAN Tunnel End Points). The VTEPs carry tenant data in L3 tunnels over the network which permits the network to support multiple tenants.The tenant data is not used in routing or switching. This aids in tenant machine movement and allows the tenants to have same IP/MAC addresses.

Information about the given VM to get to the VTEP is crucial in VXLAN protocol; therefore BGP-MP is used to carry this information across VTEPS.

Note: For port-channel/Static-channel interface, storm control will be applied on each member port. For Example: if Interface eth1 and interface eth2 is part of port-channel i.e. po1 and storm control 2mbps is applied for broadcast traffic, then the storm control settings will be applied on each member port and broadcast traffic on each member port will be rate limited to 2mbps each.

Topology

The procedures in this section use the topology in Figure 2-126.

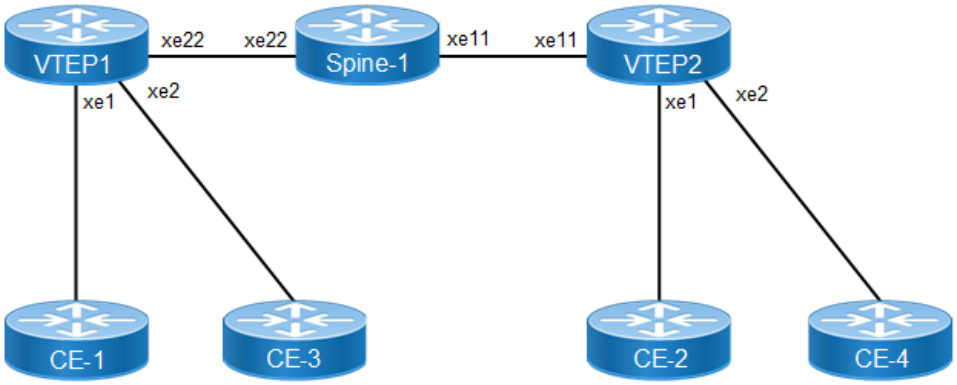

Figure 2-126: VXLAN EVPN

VTEP1

`#configure terminal`	Enter configure mode
`(config)#interface xe1`	Enter interface mode
`(config-if)#switchport`	Configure the interface as a switch port.
`(config-if)#no shutdown`	Bring the interface into operation
`(config-if)#exit`	Exit interface mode
`(config)#interface xe2`	Enter interface mode
`(config-if)#switchport`	Configure the interface as switch port.
`(config-if)#no shutdown`	Bring the interface into operation.
`(config-if)#exit`	Exit interface mode.
`(config)#interface xe22`	Enter interface mode.
`(config-if)#ip address 10.1.1.1/24`	Set an IP address on the interface.

`(config-if)#no shutdown`	Bring the interface into operation.
`(config-if)#exit`	Exit interface mode.
`(config)#interface lo`	Enter interface mode.
`(config-if)#ip address 1.1.1.1/32 secondary`	Set an IP address on the interface.
`(config-if)#no shutdown`	Bring the interface into operation.
`(config-if)#exit`	Exit interface mode.
`(config)#router isis ABC`	Create an IS-IS routing instance (ABC).
`(config-router)#is-type level-1`	Configure instance as level-1-only routing.
`(config-router)#net 49.0001.1111.1111.1111.00`	Set a Network Entity Title for this instance, specifying the area address and the system ID.
`(config-router)#exit`	Exit router mode.
`(config)#interface xe22`	Enter interface mode
`(config-if)#ip router isis ABC`	Enable IS-IS routing on an interface (ABC).
`(config-if)#isis circuit-type level-1`	Configure instance as level-1-only routing.
`(config-if)#exit`	Exit interface mode.
`(config)#interface lo`	Enter interface mode.
`(config-if)#ip router isis ABC`	Enable IS-IS routing on an interface for area 49 (ABC).
`(config-if)#isis circuit-type level-1`	Configure instance as level-1-only routing.
`(config-if)#exit`	Exit interface mode.
`(config)#mac vrf vrf_evpn_100`	Configure a new VRF named `vrf_evpn_100`.
`(config-vrf)#rd 1.1.1.1:1`	Assign the Route Distinguisher value.
`(config-vrf)#route-target both 100:1`	Configure route target to import and export the routes.
`(config-vrf)#exit`	Exit VRF mode.
`(config)#router bgp 1`	Define the routing process. The number 1 specifies the AS number of VTEP1.
`(config-router)#bgp router-id 1.1.1.1`	Configure router-id for this BGP process.
`(config-router)#neighbor 2.2.2.2 remote-as 1`	Define BGP neighbor: 2.2.2.2 is the IP address of the neighbor (VTEP2), and 1 is the neighbor's AS number.
`(config-router)# neighbor 2.2.2.2 update-source 1.1.1.1`	Define BGP neighbor: 1.1.1.1 is the peer interface.
`(config-router)#address-family l2vpn evpn`	Configure address-family L2VPN EVPN.
`(config-router-af)#neighbor 2.2.2.2 activate`	Activate the neighbor in the EVPN address family.
`(config-router-af)#exit-address-family`	Exit the address-family mode.
`(config-router)#exit`	Exit router mode.
`(config)#hardware-profile filter vxlan enable`	Enable hardware-profile filter for VXLAN.
`(config)#nvo vxlan enable`	Enable VXLAN globally on this VTEP.
`(config)#nvo vxlan vtep-ip-global 1.1.1.1`	Assign a global IP to the VTEP.
`(config)#nvo vxlan id 100 ingress-replication`	Configure a VNID on this VTEP and enter NVO mode.
`(config-nvo)#vxlan host-reachability-protocol evpn-bgp vrf_evpn_100`	Configure host-reachability-protocol as BGP-EVPN and associate the VNID with `vrf_evpn_100`.

(config-nvo)#exit	Exit NVO mode.
(config)#nvo vxlan access-if port-vlan xe1 2	Configure access-port xe1 and map vlan 2
(config-nvo-acc-if)#map vnid 100	Map VNID 100 to access-port xe1.
(config-nvo-acc-if)#exit	Exit NVO access-if mode.
(config)#nvo vxlan id 200 ingress-replication	Configure second VNID on this VTEP and enter NVO mode.
(config-nvo)#vxlan host-reachability-protocol evpn-bgp vrf_evpn_100	Configure host-reachability-protocol as BGP-EVPN and associate the VNID with vrf_evpn_100
(config-nvo)#exit	Exit NVO mode.
(config)#nvo vxlan access-if port-vlan xe2 3	Configure access-port xe2 and map vlan 3
(config-nvo-acc-if)#map vnid 200	Map VNID 200 to access-port xe2.
(config-nvo-acc-if)#exit	Exit NVO access-if mode.

Spine-1

#configure terminal	Enter configure mode.
(config)#interface xe22	Enter interface mode.
(config-if)#ip address 10.1.1.2/24	Set an IP address on the interface.
(config-if)#no shutdown	Bring the interface into operation
(config-if)#exit	Exit interface mode.
(config)#interface xe11	Enter interface mode.
(config-if)#ip address 20.1.1.2/24	Set an IP address on the interface.
(config-if)#no shutdown	Bring the interface into operation
(config-if)#exit	Exit interface mode.
(config)#router isis ABC	Create an IS-IS routing instance (ABC).
(config-router)#is-type level-1	Configure instance as level-1-only routing.
(config-router)#net 49.0001.3333.3333.3333.00	Set a Network Entity Title for this instance, specifying the area address and the system ID.
(config-router)#exit	Exit router mode.
(config)#interface xe22	Enter interface mode.
(config-if)#ip router isis ABC	Enable IS-IS routing on an interface (ABC).
(config-if)#isis circuit-type level-1	Configure instance as level-1-only routing.
(config-if)#exit	Exit interface mode.
(config)#interface xe11	Enter interface mode.
(config-if)#ip router isis ABC	Enable IS-IS routing on an interface (ABC).
(config-if)#isis circuit-type level-1	Configure instance as level-1-only routing.
(config-if)#exit	Exit interface mode.

VTEP2

#configure terminal	Enter configure mode.
(config)#interface po1	Enter interface mode

`(config-if)#switchport`	Configure the interface as a switchport.
`(config-if)#exit`	Exit interface mode
`(config)#interface xe1`	Enter interface mode.
`(config-if)#switchport`	Configure the interface as switchport.
`(config-if)#no shutdown`	Bring the interface into operation
`(config-if)#exit`	Exit interface mode.
`(config)#interface xe2`	Enter interface mode.
`(config-if)#switchport`	Configure the interface as switchport.
`(config-if)#no shutdown`	Bring the interface into operation
`(config-if)#exit`	Exit interface mode.
`(config)#interface xe11`	Enter interface mode.
`(config-if)#ip address 20.1.1.1/24`	Set an IP address on the interface.
`(config-if)#no shutdown`	Bring the interface into operation
`(config-if)#exit`	Exit interface mode.
`(config)#interface lo`	Enter interface mode.
`(config-if)#ip address 2.2.2.2/32 secondary`	Set an IP address on the interface.
`(config-if)#no shutdown`	Bring the interface into operation
`(config-if)#exit`	Exit interface mode.
`(config)#router isis ABC`	Create an IS-IS routing instance (ABC).
`(config-router)#is-type level-1`	Configure instance as level-1-only routing.
`(config-router)#net 49.0001.2222.2222.2222.00`	Set a Network Entity Title for this instance, specifying the area address and the system ID.
`(config-router)#exit`	Exit router mode.
`(config)#interface xe11`	Enter interface mode.
`(config-if)#ip router isis ABC`	Enable IS-IS routing on an interface (ABC).
`(config-if)#isis circuit-type level-1`	Configure instance as level-1-only routing.
`(config-if)#exit`	Exit interface mode.
`(config)#interface lo`	Enter interface mode.
`(config-if)#ip router isis ABC`	Enable IS-IS routing on an interface for area 49 (ABC).
`(config-if)#isis circuit-type level-1`	Configure instance as level-1-only routing.
`(config-if)#exit`	Exit interface mode.
`(config)#mac vrf vrf_evpn_100`	Configure a new VRF named `vrf_evpn_100`.
`(config-vrf)#rd 2.2.2.1:1`	Assign the Route Distinguisher value.
`(config-vrf)#route-target both 100:1`	Configure route target to import and export the routes.
`(config-vrf)#exit`	Exit VRF mode.
`(config)#router bgp 1`	Define the routing process. The number 1 specifies the AS number of VTEP1.
`(config-router)#neighbor 1.1.1.1 remote-as 1`	Define BGP neighbor: 1.1.1.1 is the IP address of the neighbor (VTEP1), and 1 is the neighbor's AS number.
`(config-router)# neighbor 1.1.1.1 update-source 2.2.2.2`	Define BGP neighbor: 2.2.2.2 is the peer interface.
`(config-router)#address-family l2vpn evpn`	Configure address-family L2VPN EVPN.

`(config-router-af)#neighbor 1.1.1.1 activate`	Activate the neighbor in the EVPN address family.
`(config-router-af)#exit-address-family`	Exit address-family mode.
`(config-router)#exit`	Exit router mode.
`(config)#hardware-profile filter vxlan enable`	Enable hardware-profile filter for VXLAN.
`(config)#nvo vxlan enable`	Enable VXLAN globally on this VTEP.
`(config)#nvo vxlan vtep-ip-global 2.2.2.2`	Assign a global IP to the VTEP.
`(config)#nvo vxlan id 100 ingress-replication`	Configure a VNID on this VTEP and enter NVO mode.
`(config-nvo)#vxlan host-reachability-protocol evpn-bgp vrf_evpn_100`	Configure host-reachability-protocol as BGP-EVPN and associate the VNID with `vrf_evpn_100`.
`(config-nvo)#exit`	Exit NVO mode.
`(config)#nvo vxlan access-if port-vlan xe1 2`	Configure access-port xe1 and map vlan 2
`(config-nvo-acc-if)#map vnid 100`	Map VNID 100 to access-port xe1.
`(config-nvo-acc-if)#exit`	Exit NVO access-if mode.
`(config)#nvo vxlan id 200 ingress-replication`	Configure second VNID on this VTEP and enter NVO mode.
`(config-nvo)#vxlan host-reachability-protocol evpn-bgp vrf_evpn_100`	Configure host-reachability-protocol as BGP-EVPN and associate the VNID with `vrf_evpn_100`
`(config-nvo)#exit`	Exit NVO mode.
`(config)#nvo vxlan access-if port-vlan xe2 3`	Configure access-port xe2 and map vlan 3
`(config-nvo-acc-if)#map vnid 200`	Map VNID 200 to access-port xe2.
`(config-nvo-acc-if)#exit`	Exit NVO access-if mode.

Validation

CE1 and CE2 have hosts configured with MAC addresses, IP addresses, and VLAN identifiers as shown below.

		VLAN	**IP Address**	**Mac Address**
VTEP1	CE-1	2	12.12.12.10	0000.0000.abab
VTEP2	CE-2	2	12.12.12.20	0000.0000.cdcd
VTEP1	CE-1	3	13.13.13.10	0000:0b60:25f2
VTEP2	CE-2	3	13.13.13.20	0000:0b60:25f3

Perform a tagged ping of VLAN 2 from CE1 to CE2 and vice-versa. Also perform a tagged ping of VLAN 3 from CE1 to CE2 and vice-versa.

VTEP Tunnel Status

```
VTEP-1#show nvo vxlan tunnel
VXLAN Network tunnel Entries
 Source           Destination      Status          Up/Down        Update

LAG as Access Port with ECMP on the Network Side

This section contains basic VXLAN EVPN configuration with LAG as an access port and ECMP on the network side.

Topology

The procedures in this section use the topology in Figure 2-127.

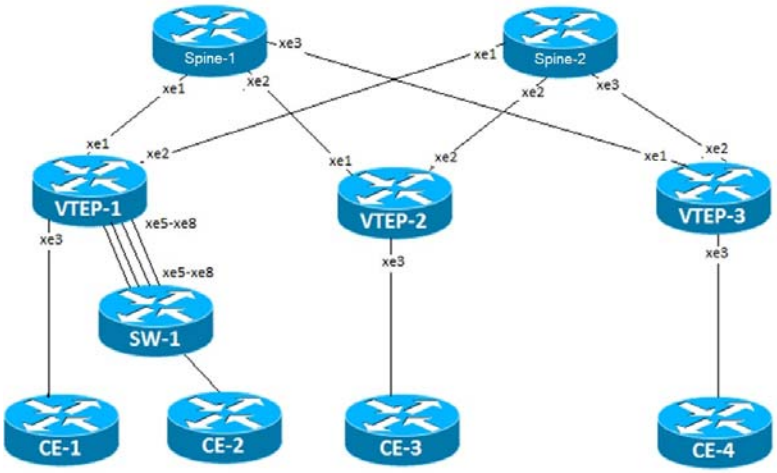

Figure 2-127: VXLAN EVPN with LAG and ECMP

SW-1

`#configure terminal`	Enter configure mode
`(config)#bridge 1 protocol ieee vlan-bridge`	Configure IEEE vlan bridge
`(config)#vlan database`	Enter into the vlan database
`(config-vlan)#vlan 2 bridge 1 state enable`	Configure vlan 2 and associate with bridge 1
`(config-vlan)#vlan 3 bridge 1 state enable`	Configure vlan 3 and associate with bridge 1
`(config-vlan)#exit`	Exit from the vlan database
`(config)#in xe41`	Enter interface mode
`(config-if)#no shutdown`	Make interface admin up
`(config-if)#switchport`	Set the interface as Layer2 port

(config-if)#bridge-group 1	Associate the Interface with bridge-group.
(config-if)#switchport mode trunk	Set the switching characteristics of this interface to trunk mode
(config-if)#switchport trunk allowed vlan add 2	Configure the VLANs that should be allowed through this interface
(config-if)#switchport trunk allowed vlan add 3	Configure the VLANs that should be allowed through this interface
(config-if)#exit	Exit interface mode.
(config)#interface po1	Enter interface mode
(config-if)#switchport	Set the interface as Layer2 port
(config-if)#exit	Exit interface mode.
(config)#in xe29	Enter interface mode
(config-if)#switchport	Set the interface as Layer2 port
(config-if)#channel-group 1 mode active	Configure the interface to be part of port channel 1
(config-if)#exit	Exit interface mode.
(config)#in xe30	Enter interface mode
(config-if)#switchport	Set the interface as Layer2 port
(config-if)#channel-group 1 mode active	Configure the interface to be part of port channel 1
(config-if)#exit	Exit interface mode.
(config)#in xe31	Enter interface mode
(config-if)#switchport	Set the interface as Layer2 port
(config-if)#channel-group 1 mode active	Configure the interface to be part of port channel 1
(config-if)#exit	Exit interface mode.
(config)#in xe32	Enter interface mode
(config-if)#switchport	Set the interface as Layer2 port
(config-if)#channel-group 1 mode active	Configure the interface to be part of port channel 1
(config-if)#exit	Exit interface mode.
(config-if)#inter po1	Enter interface mode
(config-if)#bridge-group 1	Associate the Interface with bridge-group.
(config-if)#switchport mode trunk	Set the switching characteristics of this interface to trunk mode
(config-if)#switchport trunk allowed vlan add 2	Configure the VLANs that should be allowed through this interface
(config-if)#switchport trunk allowed vlan add 3	Configure the VLANs that should be allowed through this interface
(config-if)#exit	Exit interface mode.

VTEP-1

#configure terminal	Enter configure mode
(config)#interface po1	Create interface po1
(config-if)#switchport	Configure the interface as switchport.
(config-if)#exit	Exit interface mode

(config)#interface xe3	Enter interface mode.
(config-if)#switchport	Configure the interface as switchport.
(config-if)#no shutdown	Bring the interface into operation
(config-if)#exit	Exit interface mode
(config)#interface xe5	Enter interface mode
(config-if)#switchport	Configure the interface as switchport.
(config-if)#channel-group 1 mode active	Configure the interface to be part of port channel 1
(config-if)#no shutdown	Bring the interface into operation
(config-if)#exit	Exit interface mode
(config)#interface xe6	Enter interface mode
(config-if)#switchport	Configure the interface as switchport.
(config-if)#channel-group 1 mode active	Configure the interface to be part of port channel 1
(config-if)#no shutdown	Bring the interface into operation
(config-if)#exit	Exit interface mode
(config)#interface xe7	Enter interface mode
(config-if)#switchport	Configure the interface as switchport.
(config-if)#channel-group 1 mode active	Configure the interface to be part of port channel 1
(config-if)#no shutdown	Bring the interface into operation
(config-if)#exit	Exit interface mode
(config)#interface xe8	Enter interface mode
(config-if)#switchport	Configure the interface as switchport.
(config-if)#channel-group 1 mode active	Configure the interface to be part of port channel 1
(config-if)#no shutdown	Bring the interface into operation
(config-if)#exit	Exit interface mode.
(config)#interface xe1	Enter interface mode.
(config-if)#ip address 10.1.1.0/31	Configure IP address on the interface xe1.
(config-if)#no shutdown	Bring the interface into operation
(config-if)#exit	Exit interface mode.
(config)#interface xe2	Enter interface mode.
(config-if)#ip address 10.1.1.2/31	Configure IP address on the interface xe2.
(config-if)#no shutdown	Bring the interface into operation
(config-if)#exit	Exit interface mode.
(config)#interface lo	Enter interface mode.
(config-if)#ip address 1.1.1.1/32 secondary	Configure IP address on the interface xe3.
(config-if)#no shutdown	Bring the interface into operation
(config-if)#exit	Exit interface mode.
(config)#router isis ABC	Create an IS-IS routing instance (ABC).
(config-router)#is-type level-1	Configure instance as level-1-only routing.
(config-router)#net	Set a Network Entity Title for this instance, specifying the
49.0001.1111.1111.1111.00	area address and the system ID.

(config-router)#exit	Exit router mode.
(config)#interface xe1	Enter interface mode.
(config-if)#ip router isis ABC	Enable IS-IS routing on an interface (ABC).
(config-if)#isis circuit-type level-1	Configure instance as level-1-only routing.
(config-if)#exit	Exit interface mode.
(config)#interface xe2	Enter interface mode.
(config-if)#ip router isis ABC	Enable IS-IS routing on an interface (ABC).
(config-if)#isis circuit-type level-1	Configure instance as level-1-only routing.
(config-if)#exit	Exit interface mode.
(config)#interface lo	Enter interface mode.
(config-if)#ip router isis ABC	Enable IS-IS routing on an interface for area 49 (ABC).
(config-if)#isis circuit-type level-1	Configure instance as level-1-only routing.
(config-if)#exit	Exit interface mode.
(config)#mac vrf vrf_evpn_100	Configure a new VRF named vrf_evpn_100.
(config-vrf)#rd 1.1.1.1:1	Assign the Route Distinguisher value.
(config-vrf)#route-target both 100:1	Configure route target to import and export the routes.
(config-vrf)#exit	Exit VRF mode.
(config)#router bgp 65535	Define the routing process. The number 65535 specifies the AS number of VTEP1.
(config-router)#bgp router-id 1.1.1.1	Configure router-id for this BGP process.
(config-router)#neighbor 2.2.2.2 remote-as 65535	Define BGP neighbor: 2.2.2.2 is the IP address of the neighbor (VTEP2), and 65535 is the neighbor's AS number.
(config-router)# neighbor 2.2.2.2 update-source 1.1.1.1	Define BGP neighbor: 1.1.1.1 is the peer interface.
(config-router)#neighbor 3.3.3.3 remote-as 65535	Define BGP neighbor: 3.3.3.3 is the IP address of the neighbor (VTEP3), and 65535 is the neighbor's AS number.
(config-router)# neighbor 3.3.3.3 update-source 1.1.1.1	Define BGP neighbor: 1.1.1.1 is the peer interface.
(config-router)#address-family l2vpn evpn	Configure address-family L2VPN EVPN.
(config-router-af)#neighbor 2.2.2.2 activate	Activate the neighbor at VTEP2 in the EVPN address family.
(config-router-af)#neighbor 3.3.3.3 activate	Activate the neighbor at VTEP3 in the EVPN address family.
(config-router-af)#exit-adress-family	Exit address-family mode.
(config-router)#exit	Exit router mode.
(config)#hardware-profile filter vxlan enable	Enable hardware-profile filter for VXLAN.
(config)#nvo vxlan enable	Enable VXLAN globally on this VTEP.
(config)#nvo vxlan vtep-ip-global 1.1.1.1	Assign a global IP to the VTEP.
(config)#nvo vxlan id 100001 ingress-replication	Configure a VNID on this VTEP and enter NVO mode.
(config-nvo)#vxlan host-reachability-protocol evpn-bgp vrf_evpn_100	Configure host-reachability-protocol as BGP-EVPN and associate the VNID with VRF vrf_evpn_100.
(config-nvo)#exit	Exit NVO mode.

`(config)#nvo vxlan access-if port-vlan xe3 2`	Configure access-port xe3 and map vlan 2
`(config-nvo-acc-if)#map vnid 100001`	Map VNID 100001 to access-port xe3.
`(config-nvo-acc-if)#exit`	Exit NVO access-if mode.
`(config)#nvo vxlan access-if port-vlan po1 2`	Configure access-port po1 and map vlan 2
`(config-nvo-acc-if)#map vnid 100001`	Map VNID 100001 to access-port po1.
`(config-nvo-acc-if)#exit`	Exit NVO access-if mode.
`(config)#nvo vxlan id 200001 ingress-replication`	Configure second VNID on this VTEP and enter NVO mode.
`(config-nvo)#vxlan host-reachability-protocol evpn-bgp vrf_evpn_100`	Configure host-reachability-protocol as BGP-EVPN and associate the VNID with VRF `vrf_evpn_100.`
`(config-nvo)#exit`	Exit NVO mode.
`(config)#nvo vxlan access-if port-vlan xe3 3`	Configure access-port xe3 and map vlan 3
`(config-nvo-acc-if)#map vnid 200001`	Map VNID 200001 to access-port xe3.
`(config-nvo-acc-if)#exit`	Exit NVO access-if mode.
`(config)#nvo vxlan access-if port-vlan po1 3`	Configure access-port po1 and map vlan 3
`(config-nvo-acc-if)#map vnid 200001`	Map VNID 200001 to access-port xe3.
`(config-nvo-acc-if)#exit`	Exit NVO access-if mode.

Spine-1

`#configure terminal`	Enter configure mode.
`(config)#interface lo`	Enter interface mode
`(config-if)#ip address 12.12.12.12/32 secondary`	Set an IP address on the interface.
`(config-if)#no shutdown`	Bring the interface into operation
`(config-if)#exit`	Exit interface mode.
`(config)#interface xe1`	Enter interface mode.
`(config-if)#ip address 10.1.1.1/31`	Configure IP address on the interface xe1.
`(config-if)#no shutdown`	Bring the interface into operation
`(config-if)#exit`	Exit interface mode.
`(config)#interface xe2`	Enter interface mode.
`(config-if)#ip address 20.1.1.1/31`	Configure IP address on the interface xe2.
`(config-if)#no shutdown`	Bring the interface into operation
`(config-if)#exit`	Exit interface mode.
`(config)#interface xe3`	Enter intereface mode.
`(config-if)#ip address 30.1.1.1/31`	Configure IP address on the interface xe3.
`(config-if)#no shutdown`	Bring the interface into operation
`(config-if)#exit`	Exit interface mode.
`(config)#router isis ABC`	Create an IS-IS routing instance (ABC).
`(config-router)#is-type level-1`	Configure instance as level-1-only routing.

(config-router)#net 49.0001.4444.4444.4444.00	Set a Network Entity Title for this instance, specifying the area address and the system ID.
(config-router)#exit	Exit router mode.
(config)#interface lo	Enter interface mode.
(config-if)#ip router isis ABC	Enable IS-IS routing on an interface (ABC).
(config-if)#isis circuit-type level-1	Configure instance as level-1-only routing.
(config-if)#exit	Exit interface mode.
(config)#interface xe1	Enter interface mode.
(config-if)#ip router isis ABC	Enable IS-IS routing on an interface (ABC).
(config-if)#isis circuit-type level-1	Configure instance as level-1-only routing.
(config-if)#exit	Exit interface mode.
(config)#interface xe2	Enter interface mode.
(config-if)#ip router isis ABC	Enable IS-IS routing on an interface (ABC).
(config-if)#isis circuit-type level-1	Configure instance as level-1-only routing.
(config-if)#exit	Exit interface mode.
(config)#interface xe3	Enter interface mode.
(config-if)#ip router isis ABC	Enable IS-IS routing on an interface (ABC).
(config-if)#isis circuit-type level-1	Configure instance as level-1-only routing.
(config-if)#exit	Exit interface mode.

Spine-2

#configure terminal	Enter configure mode.
(config)#interface lo	Enter interface mode.
(config-if)#ip address 13.13.13.13/32 secondary	Set an IP address on the interface.
(config-if)#no shutdown	Bring the interface into operation
(config-if)#exit	Exit interface mode.
(config)#interface xe1	Enter interface mode.
(config-if)#ip address 10.1.1.3/31	Configure IP address on the interface xe1.
(config-if)#no shutdown	Bring the interface into operation
(config-if)#exit	Exit interface mode.
(config)#interface xe2	Enter interface mode.
(config-if)#ip address 20.1.1.3/31	Configure IP address on the interface xe2.
(config-if)#no shutdown	Bring the interface into operation
(config-if)#exit	Exit interface mode.
(config)#interface xe3	Enter interface mode.
(config-if)#ip address 30.1.1.3/31	Configure IP address on the interface xe3.
(config-if)#no shutdown	Bring the interface into operation
(config-if)#exit	Exit interface mode.
(config)#router isis ABC	Create an IS-IS routing instance (ABC).
(config-router)#is-type level-1	Configure instance as level-1-only routing.

(config-router)#net 49.0001.5555.5555.5555.00	Set a Network Entity Title for this instance, specifying the area address and the system ID.
(config-router)#exit	Exit router mode.
(config)#interface lo	Enter interface mode.
(config-if)#ip router isis ABC	Enable IS-IS routing on an interface (ABC).
(config-if)#isis circuit-type level-1	Configure instance as level-1-only routing.
(config-if)#exit	Exit interface mode.
(config)#interface xe1	Enter interface mode.
(config-if)#ip router isis ABC	Enable IS-IS routing on an interface (ABC).
(config-if)#isis circuit-type level-1	Configure instance as level-1-only routing.
(config-if)#exit	Exit interface mode.
(config)#interface xe2	Enter interface mode.
(config-if)#ip router isis ABC	Enable IS-IS routing on an interface (ABC).
(config-if)#isis circuit-type level-1	Configure instance as level-1-only routing.
(config-if)#exit	Exit interface mode.
(config)#interface xe3	Enter interface mode.
(config-if)#ip router isis ABC	Enable IS-IS routing on an interface (ABC).
(config-if)#isis circuit-type level-1	Configure instance as level-1-only routing.
(config-if)#exit	Exit interface mode.

VTEP-2

#configure terminal	Enter configure mode
(config)#interface po1	Enter interface mode
(config-if)#switchport	Configure the interface as switchport
(config-if)#exit	Exit interface mode
(config)#interface xe3	Enter interface mode
(config-if)#switchport	Configure the interface as switchport.
(config-if)#no shutdown	Bring the interface into operation
(config-if)#exit	Exit interface mode.
(config)#interface xe1	Enter interface mode.
(config-if)#ip address 20.1.1.0/31	Configure IP address on the interface xe1.
(config-if)#no shutdown	Bring the interface into operation
(config-if)#exit	Exit interface mode.
(config)#interface xe2	Enter interface mode.
(config-if)#ip address 20.1.1.2/31	Configure IP address on the interface xe2.
(config-if)#no shutdown	Bring the interface into operation
(config-if)#exit	Exit interface mode.
(config)#interface lo	Enter interface mode.
(config-if)#ip address 2.2.2.2/32 secondary	Configure IP address on the interface xe3.
(config-if)#no shutdown	Bring the interface into operation

(config-if)#exit	Exit interface mode.
(config)#router isis ABC	Create an IS-IS routing instance (ABC).
(config-router)#is-type level-1	Configure instance as level-1-only routing.
(config-router)#net 49.0001.2222.2222.2222.00	Set a Network Entity Title for this instance, specifying the area address and the system ID.
(config-router)#exit	Exit router mode.
(config)#interface xe1	Enter interface mode.
(config-if)#ip router isis ABC	Enable IS-IS routing on an interface (ABC).
(config-if)#isis circuit-type level-1	Configure instance as level-1-only routing.
(config-if)#exit	Exit interface mode.
(config)#interface xe2	Enter interface mode.
(config-if)#ip router isis ABC	Enable IS-IS routing on an interface (ABC).
(config-if)#isis circuit-type level-1	Configure instance as level-1-only routing.
(config-if)#exit	Exit interface mode.
(config)#interface lo	Enter interface mode.
(config-if)#ip router isis ABC	Enable IS-IS routing on an interface for area 49 (ABC).
(config-if)#isis circuit-type level-1	Configure instance as level-1-only routing.
(config-if)#exit	Exit interface mode.
(config)#mac vrf vrf_evpn_100	Configure a new VRF named vrf_evpn_100.
(config-vrf)#rd 1.1.1.1:1	Assign the Route Distinguisher value.
(config-vrf)#route-target both 100:1	Configure route target to import and export the routes.
(config-vrf)#exit	Exit VRF mode.
(config)#router bgp 65535	Define the routing process. The number 65535 specifies the AS number of VTEP1.
(config-router)#neighbor 1.1.1.1 remote-as 65535	Define BGP neighbor: 1.1.1.1 is the IP address of the neighbor (VTEP1), and 65535 is the neighbor's AS number.
(config-router)#neighbor 1.1.1.1 update-source 2.2.2.2	Define BGP neighbor: 2.2.2.2 is the peer interface.
(config-router)#neighbor 3.3.3.3 remote-as 65535	Define BGP neighbor: 3.3.3.3 is the IP address of the neighbor (VTEP3), and 65535 is the neighbor's AS number.
(config-router)#neighbor 3.3.3.3 update-source 2.2.2.2	Define BGP neighbor: 2.2.2.2 is the peer interface.
(config-router)#address-family l2vpn evpn	Configure address-family L2VPN EVPN.
(config-router-af)#neighbor 1.1.1.1 activate	Activate the neighbor at VTEP1 in the EVPN address family.
(config-router-af)#neighbor 3.3.3.3 activate	Activate the neighbor at VTEP3 in the EVPN address family.
(config-router-af)#exit-adress-family	Exit address-family mode.
(config-router)#exit	Exit router mode.
(config)#hardware-profile filter vxlan enable	Enable hardware-profile filter for VXLAN.
(config)#nvo vxlan enable	Enable VXLAN globally on this VTEP.
(config)#nvo vxlan vtep-ip-global 2.2.2.2	Assign a global IP to the VTEP.

`(config)#nvo vxlan id 100001 ingress-replication`	Configure a VNID on this VTEP and enter NVO mode.
`(config-nvo)#vxlan host-reachability-protocol evpn-bgp vrf_evpn_100`	Configure host-reachability-protocol as BGP-EVPN and associate the VNID with VRF `vrf_evpn_100`.
`(config-nvo)#exit`	Exit NVO mode.
`(config)#nvo vxlan access-if port-vlan xe3 2`	Configure access-port xe3 and map vlan 2
`(config-nvo-acc-if)#map vnid 100001`	Map VNID 100001 to access-port xe3.
`(config-nvo-acc-if)#exit`	Exit NVO access-if mode.
`(config)#nvo vxlan id 200001 ingress-replication`	Configure second VNID on this VTEP and enter NVO mode.
`(config-nvo)#vxlan host-reachability-protocol evpn-bgp vrf_evpn_100`	Configure host-reachability-protocol as BGP-EVPN and associate the VNID with VRF `vrf_evpn_100.`
`(config-nvo)#exit`	Exit NVO mode.
`(config)#nvo vxlan access-if port-vlan xe3 3`	Configure access-port xe3 and map vlan 3
`(config-nvo-acc-if)#map vnid 200001`	Map VNID 200001 to access-port xe3.
`(config-nvo-acc-if)#exit-adress-family`	Exit NVO access-if mode.

VTEP-3

`#configure terminal`	Enter configure mode.
`(config)#interface xe3`	Enter interface mode.
`(config-if)#switchport`	Configure the interface as switchport.
`(config-if)#no shutdown`	Bring the interface into operation
`(config-if)#exit`	Exit interface mode.
`(config)#interface xe1`	Enter interface mode.
`(config-if)#ip address 30.1.1.0/31`	Configure IP address on the interface xe1.
`(config-if)#no shutdown`	Bring the interface into operation
`(config-if)#exit`	Exit interface mode.
`(config)#interface xe2`	Enter interface mode.
`(config-if)#ip address 30.1.1.2/31`	Configure IP address on the interface xe2.
`(config-if)#no shutdown`	Bring the interface into operation
`(config-if)#exit`	Exit interface mode.
`(config)#interface lo`	Enter interface mode.
`(config-if)#ip address 3.3.3.3/32 secondary`	Configure IP address on the loopback interface.
`(config-if)#no shutdown`	Bring the interface into operation
`(config-if)#exit`	Exit interface mode.
`(config)#router isis ABC`	Create an IS-IS routing instance (ABC).
`(config-router)#is-type level-1`	Configure instance as level-1-only routing.
`(config-router)#net 49.0001.3333.3333.3333.00`	Set a Network Entity Title for this instance, specifying the area address and the system ID.
`(config-router)#exit`	Exit router mode.

(config)#interface xe1	Enter interface mode.
(config-if)#ip router isis ABC	Enable IS-IS routing on an interface (ABC).
(config-if)#isis circuit-type level-1	Configure instance as level-1-only routing.
(config-if)#exit	Exit interface mode.
(config)#interface xe2	Enter interface mode.
(config-if)#ip router isis ABC	Enable IS-IS routing on an interface (ABC).
(config-if)#isis circuit-type level-1	Configure instance as level-1-only routing.
(config-if)#exit	Exit interface mode.
(config)#interface lo	Enter interface mode.
(config-if)#ip router isis ABC	Enable IS-IS routing on an interface for area 49 (ABC).
(config-if)#isis circuit-type level-1	Configure instance as level-1-only routing.
(config-if)#exit	Exit interface mode.
(config)#mac vrf vrf_evpn_100	Configure a new VRF named vrf_evpn_100.
(config-vrf)#rd 1.1.1.1:1	Assign the Route Distinguisher value.
(config-vrf)#route-target both 100:1	Configure route target to import and export the routes.
(config-vrf)#exit	Exit VRF mode.
(config)#router bgp 65535	Define the routing process. The number 65535 specifies the AS number of VTEP1.
(config-router)#neighbor 1.1.1.1 remote-as 65535	Define BGP neighbor: 1.1.1.1 is the IP address of the neighbor (VTEP1), and 65535 is the neighbor's AS number.
(config-router)#neighbor 1.1.1.1 update-source 3.3.3.3	Define BGP neighbor: 3.3.3.3 is the peer interface.
(config-router)#neighbor 2.2.2.2 remote-as 65535	Define BGP neighbor: 2.2.2.2 is the IP address of the neighbor (VTEP3), and 65535 is the neighbor's AS number.
(config-router)#neighbor 2.2.2.2 update-source 3.3.3.3	Define BGP neighbor: 3.3.3.3 is the peer interface.
(config-router)#address-family l2vpn evpn	Configure address-family L2VPN EVPN.
(config-router-af)#neighbor 1.1.1.1 activate	Activate the neighbor at VTEP1 in the EVPN address family.
(config-router-af)#neighbor 2.2.2.2 activate	Activate the neighbor at VTEP2 in the EVPN address family.
(config-router-af)#exit-adress-family	Exit address-family mode.
(config-router)#exit	Exit router mode.
(config)#hardware-profile filter vxlan enable	Enable hardware-profile filter for VXLAN.
(config)#nvo vxlan enable	Enable VXLAN globally on this VTEP.
(config)#nvo vxlan vtep-ip-global 3.3.3.3	Assign a global IP to the VTEP.
(config)#nvo vxlan id 100001 ingress-replication	Configure a VNID on this VTEP and enter NVO mode.
(config-nvo)#vxlan host-reachability-protocol evpn-bgp vrf_evpn_100	Configure host-reachability-protocol as BGP-EVPN and associate the VNID with VRF vrf_evpn_100.
(config-nvo)#exit	Exit NVO mode.
(config)#nvo vxlan access-if port-vlan xe3 2	Configure access-port xe3 and map vlan 2
(config-nvo-acc-if)#map vnid 100001	Map VNID 100001 to access-port xe3.

`(config-nvo-acc-if)#exit-address-family`	Exit NVO access-if mode.
`(config)#nvo vxlan id 200001 ingress-replication`	Configure second VNID on this VTEP and enter NVO mode.
`(config-nvo)#vxlan host-reachability-protocol evpn-bgp vrf_evpn_100`	Configure host-reachability-protocol as BGP-EVPN and associate the VNID with VRF `vrf_evpn_100`
`(config-nvo)#exit`	Exit NVO mode.
`(config)#nvo vxlan access-if port-vlan xe3 3`	Configure access-port xe3 and map vlan 3
`(config-nvo-acc-if)#map vnid 200001`	Map VNID 200001 to access-port xe3.
`(config-nvo-acc-if)#exit`	Exit NVO access-if mode.

Validation

CE1, CE2, CE3, and CE4 have hosts configured with MAC addresses, IP addresses, and VLAN identifiers as shown below.

		VLAN	IP Address	MAC Address
VTEP1	CE-1	2	12.12.12.10	0000.0000.aaaa
VTEP1	CE-2	2	12.12.12.20	0000.0000.bbbb
VTEP2	CE-3	2	12.12.12.30	0000.0000.cccc
VTEP3	CE-4	2	12.12.12.40	0000.0000.dddd
VTEP1	CE-1	3	14.14.14.10	0000.058e.2181
VTEP1	CE-2	3	14.14.14.20	0000.058e.2182
VTEP2	CE-3	3	14.14.14.30	0000.058e.2183
VTEP3	CE-4	3	14.14.14.40	0000.058e.2184

Perform a tagged ping of VLAN 2 from CE1 to CE2,CE3 and CE4 and vice-versa. Also perform a tagged ping of VLAN 3 from CE1 to CE2, CE3 and CE4 and vice-versa.

VTEP Tunnel Status

```

CHAPTER 3 VxLAN Multi-Homing Configuration

This chapter contains the configurations for VxLAN Multi-homing feature.

Overview

VxLAN EVPN Multi-homing features enables to connect a CE/Host node to two VTEPs with all-active redundancy mode. A redundant VTEP device can provide network service to the customer site as soon as a failure is detected. The failure can be link or node failure. If one VTEP goes down, other will forward the entire traffic.

Below are Multi-homing concepts:

- Ethernet Segment: Set of links which connect host/CE to two active-active multi-homed VTEP (only two VTEPs are supported) which appears as LACP link for host.
- Ethernet Segment Identifier: Ethernet Segment Identifier (ESI) which is a 10 octet-value, which can be configured in two ways, system MAC is configured as esi in case of Dynamic LAG and 10-octet ESI format configuration is used on physical interface ES.
- Ethernet Segment Route (ES route): When a multi-homed CE is configured as an VXLAN access-port, Ethernet segment route is sent. The main purpose of this route is to discover other VTEPs which share the ES and to perform DF election.
- Ethernet A-D route per ESI: This route is used for Fast Convergence and Split Horizon.
- Ethernet A-D route per EVI: This route is used for load sharing between DF and NON-DF by the remote VTEPs

Topology

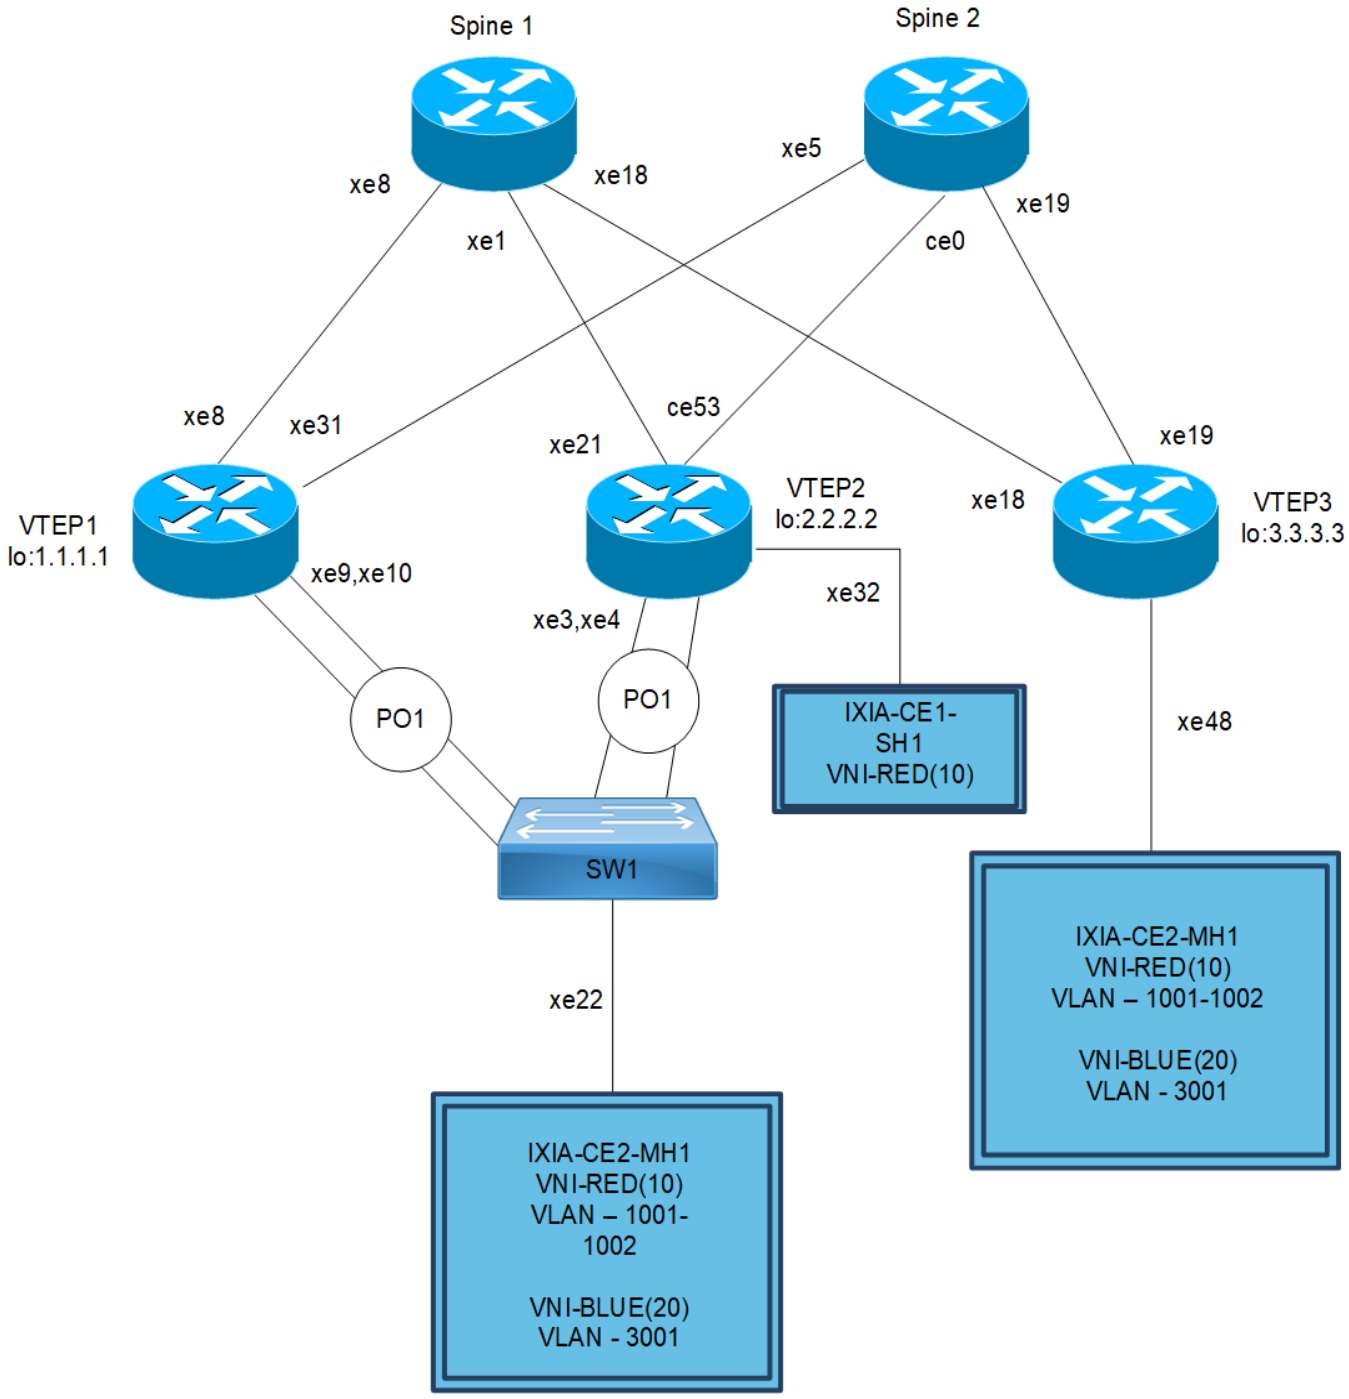

Figure 3-128: VxLAN-Multihoming

ESI can be configured in below two ways

Ethernet Segment through Dynamic LAG interface

`#configure terminal`	Enter Configure mode.
`(config)#interface po1`	Enter Interface mode for po1
`(config-if)#switchport`	Make it L2 interface
`(config-if)#evpn multi-homed system-mac 8899.4400.6745`	Configure system mac as ESI value for LAG (po1) interface
`(config-if)#exit`	Exit Interface mode.

OR

Ethernet Segment through Physical or Static LAG interface

`#configure terminal`	Enter Configure mode.
`(config)#interface xe41`	Enter Interface mode for xe41
`(config-if)#switchport`	Make it L2 interface
`(config-if)# evpn multi-homed esi 00:01:02:03:04:05:06:07:08`	Configure 9-octet ESI value for xe41 interface (in static config, out of 10-octet ESI value, first octet is reserved)
`(config-if)#exit`	Exit Interface mode.

VTEP1

(Multi-homed group1) – Part of both Multi-homed with po1 (MH1)

Hardware Profile and Generic Configuration

`#configure terminal`	Enter Configure mode.
`(config)#hardware-profile filter vxlan enable`	Enable hardware-profile filter for VXLAN.
`(config)#hardware-profile filter vxlan-mh enable`	Enable hardware-profile filter for VXLAN multi-homing.
`(config)#hardware-profile filter egress-ipv4 enable`	Enable hardware-profile filter for egress IPv4.
`(config)#evpn vxlan multihoming enable`	Enable Multihoming, save configs and reboot the board for multihoming to be effective
`(config)#hardware-profile statistics ac-lif enable`	Enable ac-lif for VxLAN access-if port counters
`(config)#qos enable`	Enabling QoS

Interface and Loopback Configuration

`(config)#interface po1`	Enter Interface mode for po1 (MH1)
`(config-if)#switchport`	Make it L2 interface
`(config-if)# evpn multi-homed system-mac 0000.0000.1111`	Configure system MAC as ESI value for LAG (po1) interface
`(config-if)#exit`	Exit Interface mode and return to Configure mode.

(config)#interface xe9	Enter Interface mode for xe9
(config-if)#channel-group 1 mode active	Make it member port of po1
(config-if)#exit	Exit Interface mode and return to Configure mode.
(config)#interface xe10	Enter Interface mode for xe10
(config-if)#channel-group 1 mode active	Make it member port of po1
(config-if)#exit	Exit Interface mode and return to Configure mode.
(config)#interface lo	Enter Interface mode for lo
(config-if)#ip address 1.1.1.1/32 secondary	Configure loopback ip address as 1.1.1.1 for VTEP1
(config-if)#exit	Exit Interface mode and return to Configure mode.
(config)#interface xe8	Enter Interface mode for xe8
(config-if)#ip address 10.10.10.1/24	Configure IP address as 10.10.10.1 on network side of Spine1
(config-if)#exit	Exit Interface mode and return to Configure mode.
(config)#interface xe31	Enter Interface mode for xe31
(config-if)#ip address 20.20.20.1/24	Configure IP address as 20.20.20.1 on network side of Spine2
(config-if)#exit	Exit Interface mode and return to Configure mode.

OSPF Configuration

(config)#router ospf 100	Enter into router OSPF mode
(config-router)#ospf router-id 1.1.1.1	Configure router-id as 1.1.1.1 (lo ip address)
(config-router)#network 1.1.1.1/32 area 0.0.0.0	Add 1.1.1.1 (lo IP address) network into area 0
(config-router)#network 10.10.10.0/24 area 0.0.0.0	Add 10.10.10.0 (Spine1) network into area 0
(config-router)#network 20.20.20.0/24 area 0.0.0.0	Add 20.20.20.0 (Spine2) network into area 0
(config-router)#bfd all-interfaces	Enabling BFD on all OSPF interface for fast convergence
(config-if)#exit	Exit Interface mode and return to Configure mode.

BGP Configuration

(config)#router bgp 500	Enter into Router BGP mode
(config-router)#bgp router-id 1.1.1.1	Configure router-id as 1.1.1.1 (lo IP address)
(config-router)#network 1.1.1.1/32	Advertise loopback network into BGP for VTEP ID reachability
(config-router)#neighbor 2.2.2.2 remote-as 500	Specify a VTEP2 loopback IP address and remote-as defined
(config-router)#neighbor 2.2.2.2 update-source lo	Configure update as loopback for VTEP2
(config-router)#neighbor 2.2.2.2 advertisement-interval 0	Configure advertisement-interval as 0 for fast convergence for VTEP2
(config-router)#neighbor 3.3.3.3 remote-as 500	Specify a VTEP3 loopback IP address and remote-as defined
(config-router)#neighbor 3.3.3.3 update-source lo	Configure update as loopback for VTEP3

(config-router)#neighbor 3.3.3.3 advertisement-interval 0	Configure advertisement-interval as 0 for fast convergence for VTEP3
(config-router)#address-family l2vpn evpn	Enter into L2VPN EVPN address family mode
(config-router-af)#neighbor 2.2.2.2 activate	Activate 2.2.2.2 (VTEP2) into L2VPN evpn address family mode
(config-router-af)#neighbor 3.3.3.3 activate	Activate 3.3.3.3 (VTEP3) into L2VPN evpn address family mode
(config-router-af)#exit-address-family	Exit from L2VPN address family mode
(config-router)#exit	Exit from Router BGP mode and enter into config mode

VRF Configuration

(config)#mac vrf VRF1	Create mac routing/forwarding instance with VRF1 name and enter into VRF mode
(config-vrf)#rd 1.1.1.1:11	Assign RD value
(config-vrf)#route-target both 9.9.9.9:100	Assign route-target value for same for import and export. Should be same on all node for VRF1
(config-vrf)#exit	Exit from VRF mode
(config)#mac vrf VRF2	Create MAC routing/forwarding instance with VRF1 name and enter into VRF mode
(config-vrf)#rd 1.1.1.1:21	Assign RD value
(config-vrf)#route-target both 90.90.90.90:100	Assign route-target value for same for import and export
(config-vrf)#exit	Exit from VRF mode

VxLAN Configuration

(config)#nvo vxlan enable	Enable VxLAN
(config)#evpn esi hold-time 60	Configure ESI hold time to allow tunnel to come up at the time of VxLAN initialization before making the ESI up
(config)#nvo vxlan vtep-ip-global 1.1.1.1	Configure Source VTEP-IP-global configuration
(config)#nvo vxlan id 10 ingress-replication inner-vid-disabled	Configure VxLAN Network identifier with/without inner-VID-disabled configure and enter into VxLAN tenant mode
(config-nvo)#vxlan host-reachability-protocol evpn-bgp VRF1	Assign VRF for EVPN-BGP to carry EVPN route
(config-nvo)#vni-name VNI-RED	Configure VNI-name as VNI-RED
(config-nvo)#exit	Exit from VxLAN tenant mode and enter into configuration mode.
(config)#nvo vxlan id 20 ingress-replication inner-vid-disabled	Configure VxLAN Network identifier with/without inner-VID-disabled configure and enter into VxLAN tenant mode
(config-nvo)#vxlan host-reachability-protocol evpn-bgp VRF2	Assign VRF for EVPN-BGP to carry EVPN route
(config-nvo)#vni-name VNI-BLUE	Configure VNI-name as VNI-BLUE
(config-nvo)#exit	Exit from VxLAN tenant mode and enter into configuration mode.
(config)#nvo vxlan access-if port-vlan po1 1001	Enable port-VLAN mapping i.e. access port to outer-VLAN (SVLAN) - Multihomed access port

(config-nvo-acc-if)#map vni-name VNI-RED	Map VxLAN Identified to access-port for VxLAN
(config-nvo-acc-if)#exit	Exit from VxLAN access-interface mode and enter into configuration mode
(config)#nvo vxlan access-if port-vlan po1 1002	Enable port-VLAN mapping i.e. access port to outer-VLAN (SVLAN) - Multihomed access port
(config-nvo-acc-if)#map vni-name VNI-RED	Map VxLAN Identified to access-port for VxLAN
(config-nvo-acc-if)#exit	Exit from VxLAN access-interface mode and enter into configuration mode
(config)#nvo vxlan access-if port-vlan po1 3001	Enable port-VLAN mapping i.e. access port to outer-VLAN (SVLAN) - Multihomed access port
(config-nvo-acc-if)#map vni-name VNI-BLUE	Map VxLAN Identified to access-port for VxLAN
(config-nvo-acc-if)#exit	Exit from VxLAN access-interface mode and enter into configuration mode
(config)#exit	Exit from configuration mode

VTEP2

(Multi-homed group1) – Part of both Multi-homed with po1 (MH1). And it has xe32 as single home access-if port (SH2)

Hardware Profile and Generic Configuration

#configure terminal	Enter Configure mode.
(config)#hardware-profile filter vxlan enable	Enable hardware-profile filter for VxLAN.
(config)#hardware-profile filter vxlan-mh enable	Enable hardware-profile filter for VxLAN multi-homing.
(config)#hardware-profile filter egress-ipv4 enable	Enable hardware-profile filter for egress IPv4.
(config)#evpn vxlan multihoming enable	Enable Multihoming, save configs and reboot the board for multihoming to be effective
(config)#hardware-profile statistics ac-lif enable	Enable ac-lif for VxLAN access-if port counters
(config)#qos enable	Enabling QoS

Interface and Loopback Configuration

(config)#interface po1	Enter Interface mode for po1 (MH1)
(config-if)#switchport	Make it L2 interface
(config-if)# evpn multi-homed system-mac 0000.0000.1111	Configure system MAC as ESI value for LAG (po1) interface
(config-if)#exit	Exit Interface mode and return to Configure mode.
(config)#interface xe3	Enter Interface mode for xe3
(config-if)#channel-group 1 mode active	Make it member port of po1
(config-if)#exit	Exit Interface mode and return to Configure mode.
(config)#interface xe4	Enter Interface mode for xe4
(config-if)#channel-group 1 mode active	Make it member port of po1

(config-if)#exit	Exit Interface mode and return to Configure mode.
(config)#interface xe32	Enter Interface mode for xe32 (SH2)
(config-if)#switchport	Make it L2 interface
(config-if)#exit	Exit Interface mode and return to Configure mode.
(config)#interface lo	Enter Interface mode for lo
(config-if)#ip address 2.2.2.2/32 secondary	Configure loopback IP address as 2.2.2.2 for VTEP2
(config-if)#exit	Exit Interface mode and return to Configure mode.
(config)#interface xe21	Enter Interface mode for xe21
(config-if)#ip address 30.30.30.1/24	Configure IP address as 30.30.30.1 on network side of Spine1
(config-if)#exit	Exit Interface mode and return to Configure mode.
(config)#interface ce53	Enter Interface mode for ce53
(config-if)#ip address 40.40.40.1/24	Configure IP address as 40.40.40.1 on network side of Spine2
(config-if)#exit	Exit Interface mode and return to Configure mode.

OSPF Configuration

(config)#router ospf 100	Enter into router OSPF mode
(config-router)#ospf router-id 2.2.2.2	Configure router-id as 2.2.2.2 (lo IP address)
(config-router)#network 2.2.2.2/32 area 0.0.0.0	Add 2.2.2.2 (lo IP address) network into area 0
(config-router)#network 30.30.30.0/24 area 0.0.0.0	Add 30.30.30.0 (Spine1) network into area 0
(config-router)#network 40.40.40.0/24 area 0.0.0.0	Add 40.40.40.0 (Spine2) network into area 0
(config-router)#bfd all-interfaces	Enabling BFD on all OSPF interface for fast convergence
(config-if)#exit	Exit Interface mode and return to Configure mode.

BGP Configuration

(config)#router bgp 500	Enter into Router BGP mode
(config-router)#bgp router-id 2.2.2.2	Configure router-id as 2.2.2.2 (lo IP address)
(config-router)#network 2.2.2.2/32	Advertise loopback network into BGP for VTEP ID reachability
(config-router)#neighbor 1.1.1.1 remote-as 500	Specify a VTEP1 loopback IP address and remote-as defined
(config-router)#neighbor 1.1.1.1 update-source lo	Configure update as loopback for VTEP1
(config-router)#neighbor 1.1.1.1 advertisement-interval 0	Configure advertisement-interval as 0 for fast convergence for VTEP1
(config-router)#neighbor 3.3.3.3 remote-as 500	Specify a VTEP3 loopback IP address and remote-as defined
(config-router)#neighbor 3.3.3.3 update-source lo	Configure update as loopback for VTEP3
(config-router)#neighbor 3.3.3.3 advertisement-interval 0	Configure advertisement-interval as 0 for fast convergence for VTEP3
(config-router)#address-family l2vpn evpn	Enter into L2VPN EVPN address family mode

`(config-router-af)#neighbor 1.1.1.1 activate`	Activate 1.1.1.1(VTEP1) into L2VPN evpn address family mode
`(config-router-af)#neighbor 3.3.3.3 activate`	Activate 3.3.3.3(VTEP3) into L2VPN evpn address family mode
`(config-router-af)#exit-address-family`	Exit from L2VPN address family mode
`(config-router)#exit`	Exit from Router BGP mode and enter into config mode

VRF Configuration

`(config)# mac vrf VRF1`	Create mac routing/forwarding instance with VRF1 name and enter into VRF mode
`(config-vrf)#rd 2.2.2.2:11`	Assign RD value
`(config-vrf)#route-target both 9.9.9.9:100`	Assign route-target value for same for import and export. Should be same on all node for VRF1
`(config-vrf)#exit`	Exit from VRF mode
`(config)#mac vrf VRF2`	Create MAC routing/forwarding instance with VRF1 name and enter into VRF mode
`(config-vrf)#rd 2.2.2.2:21`	Assign RD value
`(config-vrf)#route-target both 90.90.90.90:100`	Assign route-target value for same for import and export
`(config-vrf)#exit`	Exit from VRF mode

VxLAN Configuration

`(config)#nvo vxlan enable`	Enable VxLAN
`(config)#evpn esi hold-time 60`	Configure ESI hold time to allow tunnel to come up at the time of VxLAN initialization before making the ESI up
`(config)#nvo vxlan vtep-ip-global 2.2.2.2`	Configure Source VTEP-IP-global configuration
`(config)#nvo vxlan id 10 ingress-replication inner-vid-disabled`	Configure VxLAN Network identifier with/without inner-VID-disabled configure and enter into VxLAN tenant mode
`(config-nvo)#vxlan host-reachability-protocol evpn-bgp VRF1`	Assign VRF for EVPN-BGP to carry EVPN route
`(config-nvo)#vni-name VNI-RED`	Configure VNI-name as VNI-RED
`(config-nvo)#exit`	Exit from VxLAN tenant mode and enter into configuration mode.
`(config)#nvo vxlan id 20 ingress-replication inner-vid-disabled`	Configure VxLAN Network identifier with/without inner-VID-disabled configure and enter into VxLAN tenant mode
`(config-nvo)#vxlan host-reachability-protocol evpn-bgp VRF2`	Assign VRF for EVPN-BGP to carry EVPN route
`(config-nvo)#vni-name VNI-BLUE`	Configure VNI-name as VNI-BLUE
`(config-nvo)#exit`	Exit from VxLAN tenant mode and enter into configuration mode.
`(config)#nvo vxlan access-if port-vlan po1 1001`	Enable port-VLAN mapping i.e. access port to outer-VLAN (SVLAN) - Multihomed access port
`(config-nvo-acc-if)#map vni-name VNI-RED`	Map VxLAN Identified to access-port for VxLAN
`(config-nvo-acc-if)#exit`	Exit from VxLAN access-interface mode and enter into configuration mode

(config)#nvo vxlan access-if port-vlan po1 1002	Enable port-VLAN mapping i.e. access port to outer-VLAN (SVLAN) - Multihomed access port
(config-nvo-acc-if)#map vni-name VNI-RED	Map VxLAN Identified to access-port for VxLAN
(config-nvo-acc-if)#exit	Exit from VXLAN access-interface mode and enter into configuration mode
(config)#nvo vxlan access-if port-vlan po1 3001	Enable port-VLAN mapping i.e. access port to outer-VLAN (SVLAN) - Multihomed access port
(config-nvo-acc-if)#map vni-name VNI-BLUE	Map VxLAN Identified to access-port for VxLAN
(config-nvo-acc-if)#exit	Exit from VxLAN access-interface mode and enter into configuration mode
(config)#nvo vxlan access-if port xe32	Enable port-VLAN mapping i.e. access port to outer-VLAN (SVLAN) - Multihomed access port
(config-nvo-acc-if)#map vni-name VNI-RED	Map VxLAN Identified to access-port for VxLAN
(config-nvo-acc-if)#exit	Exit from VxLAN access-interface mode and enter into configuration mode
(config)#exit	Exit from configuration mode

VTEP3

It has xe48 as Single home access-if port (SH2)

Hardware Profile and Generic Configuration

#configure terminal	Enter Configure mode.
(config)#hardware-profile filter vxlan enable	Enable hardware-profile filter for VxLAN.
(config)#hardware-profile filter vxlan-mh enable	Enable hardware-profile filter for VxLAN multi-homing.
(config)#hardware-profile filter egress-ipv4 enable	Enable hardware-profile filter for egress IPv4.
(config)#evpn vxlan multihoming enable	Enable Multihoming, save configs and reboot the board for multihoming to be effective
(config)#hardware-profile statistics ac-lif enable	Enable ac-lif for VxLAN access-if port counters
(config)#qos enable	Enabling QoS

Interface and loopback configuration

(config)#interface xe48	Enter Interface mode for xe48 (SH3)
(config-if)#switchport	Make it L2 interface
(config-if)#exit	Exit Interface mode and return to Configure mode.
(config)#interface lo	Enter Interface mode for lo
(config-if)#ip address 3.3.3.3/32 secondary	Configure loopback IP address as 3.3.3.3 for VTEP3
(config-if)#exit	Exit Interface mode and return to Configure mode.
(config)#interface xe18	Enter Interface mode for xe18
(config-if)#ip address 50.50.50.1/24	Configure IP address as 50.50.50.1 on network side of Spine1

(config-if)#exit	Exit Interface mode and return to Configure mode.
(config)#interface xe19	Enter Interface mode for xe19
(config-if)#ip address 60.60.60.1/24	Configure IP address as 60.60.60.1 on network side of Spine2
(config-if)#exit	Exit Interface mode and return to Configure mode.

OSPF Configuration

(config)#router ospf 100	Enter into router OSPF mode
(config-router)#ospf router-id 2.2.2.2	Configure router-ID as 2.2.2.2 (lo IP address)
(config-router)#network 2.2.2.2/32 area 0.0.0.0	Add 2.2.2.2 (lo IP address) network into area 0
(config-router)#network 50.50.50.0/24 area 0.0.0.0	Add 50.50.50.0 (Spine1) network into area 0
(config-router)#network 60.60.60.0/24 area 0.0.0.0	Add 60.60.60.0 (Spine2) network into area 0
(config-router)#bfd all-interfaces	Enabling BFD on all OSPF interface for fast convergence
(config-if)#exit	Exit Interface mode and return to Configure mode.

BGP Configuration

(config)#router bgp 500	Enter into Router BGP mode
(config-router)#bgp router-id 3.3.3.3	Configure router-ID as 3.3.3.3 (lo ip address)
(config-router)#network 3.3.3.3/32	Advertise loopback network into BGP for VTEP ID reachability
(config-router)#neighbor 1.1.1.1 remote-as 500	Specify a VTEP1 loopback IP address and remote-as defined
(config-router)#neighbor 1.1.1.1 update-source lo	Configure update as loopback for VTEP1
(config-router)#neighbor 1.1.1.1 advertisement-interval 0	Configure advertisement-interval as 0 for fast convergence for VTEP1
(config-router)#neighbor 2.2.2.2 remote-as 500	Specify a VTEP2 loopback IP address and remote-as defined
(config-router)#neighbor 2.2.2.2 update-source lo	Configure update as loopback for VTEP2
(config-router)#neighbor 2.2.2.2 advertisement-interval 0	Configure advertisement-interval as 0 for fast convergence for VTEP3
(config-router)#address-family l2vpn evpn	Enter into L2VPN EVPN address family mode
(config-router-af)#neighbor 1.1.1.1 activate	Activate 1.1.1.1 (VTEP1) into L2VPN evpn address family mode
(config-router-af)#neighbor 2.2.2.2 activate	Activate 2.2.2.2 (VTEP2) into L2VPN evpn address family mode
(config-router-af)#exit-address-family	Exit from L2VPN address family mode
(config-router)#exit	Exit from Router BGP mode and enter into config mode

VRF Configuration

(config)# mac vrf VRF1	Create MAC routing/forwarding instance with VRF1 name and enter into VRF mode
(config-vrf)#rd 3.3.3.3:11	Assign RD value
(config-vrf)#route-target both 9.9.9.9:100	Assign route-target value for same for import and export. Should be same on all node for VRF1
(config-vrf)#exit	Exit from VRF mode
(config)#mac vrf VRF2	Create MAC routing/forwarding instance with VRF2 name and enter into VRF mode
(config-vrf)#rd 3.3.3.3:21	Assign RD value
(config-vrf)#route-target both 90.90.90.90:100	Assign route-target value for same for import and export
(config-vrf)#exit	Exit from VRF

VxLAN Configuration

(config)#nvo vxlan enable	Enable VxLAN
(config)#nvo vxlan vtep-ip-global 3.3.3.3	Configure Source VTEP-IP-global configuration
(config)#nvo vxlan id 10 ingress-replication inner-vid-disabled	Configure VxLAN Network identifier with/without inner-VID-disabled configure and enter into VxLAN tenant mode
(config-nvo)#vxlan host-reachability-protocol evpn-bgp VRF1	Assign VRF for EVPN-BGP to carry EVPN route
(config-nvo)#vni-name VNI-RED	Configure VNI-name as VNI-RED
(config-nvo)#exit	Exit from VxLAN tenant mode and enter into configuration mode.
(config)#nvo vxlan id 20 ingress-replication inner-vid-disabled	Configure VxLAN Network identifier with/without inner-VID-disabled configure and enter into VxLAN tenant mode
(config-nvo)#vxlan host-reachability-protocol evpn-bgp VRF2	Assign VRF for EVPN-BGP to carry EVPN route
(config-nvo)#vni-name VNI-BLUE	Configure VNI-name as VNI-BLUE
(config-nvo)#exit	Exit from VxLAN tenant mode and enter into configuration mode.
(config)#nvo vxlan access-if port-vlan xe48 1001	Enable port-VLAN mapping i.e. access port to outer-VLAN (SVLAN) - Multihomed access port
(config-nvo-acc-if)#map vni-name VNI-RED	Map VxLAN Identified to access-port for VxLAN
(config-nvo-acc-if)#exit	Exit from VxLAN access-interface mode and enter into configuration mode
(config)#nvo vxlan access-if port-vlan xe48 1002	Enable port-VLAN mapping i.e. access port to outer-VLAN (SVLAN) - Multihomed access port
(config-nvo-acc-if)#map vni-name VNI-RED	Map VxLAN Identified to access-port for VxLAN
(config-nvo-acc-if)#exit	Exit from VxLAN access-interface mode and enter into configuration mode
(config)#nvo vxlan access-if port-vlan xe48 3001	Enable port-VLAN mapping i.e. access port to outer-VLAN (SVLAN) - Multihomed access port
(config-nvo-acc-if)#map vni-name VNI-BLUE	Map VxLAN Identified to access-port for VxLAN

`(config-nvo-acc-if)#exit`	Exit from VxLAN access-interface mode and enter into configuration mode
`(config)#exit`	Exit from configuration mode

Switch (CE2)

Multihomed to 2-VTEPs (VTEP1 and VTEP2)

`#configure terminal`	Enter Configure mode.
`(config)#bridge 1 protocol ieee vlan-bridge`	Configure IEEE VLAN bridge
`(config)#vlan 1001-1002 bridge 1 state enable`	Configure VLANs from 1001-1002 and associate with bridge 1
`(config)#vlan 3001 bridge 1 state enable`	Configure VLANs from 3001 and associate with bridge 1
`(config)#interface xe22`	Enter Interface mode for xe22
`(config-if)#switchport`	Make xe22 as L2 port by configuring switchport
`(config-if)#bridge-group 1`	Associate xe22 to bridge 1
`(config-if)#switchport mode hybrid`	Configure xe22 as hybrid port
`(config-if)#switchport hybrid allowed vlan add 1001-1002,3001 egress-tagged enable`	Allow 1001-1002 and 3001 configured VLANs on xe22
`(config-if)#exit`	Exit Interface mode and return to Configure mode.
`(config)#interface po1`	Enter Interface mode for po1
`(config-if)#switchport`	Make po1 as L2 port by configuring switchport
`(config-if)#bridge-group 1`	Associate po1 to bridge 1
`(config-if)#switchport mode hybrid`	Configure po1 as hybrid port
`(config-if)#switchport hybrid allowed vlan add 1001-1002,3001 egress-tagged enable`	Allow 1001-1002 and 3001 configured VLANs on po1
`(config-if)#exit`	Exit Interface mode and return to Configure mode.
`(config)#interface xe3`	Enter Interface mode for xe3
`(config-if)#channel-group 1 mode active`	Make it member port of po1
`(config)#interface xe4`	Enter Interface mode for xe4
`(config-if)#channel-group 1 mode active`	Make it member port of po1
`(config)#exit`	Exit from configuration mode
`(config)#interface xe9`	Enter Interface mode for xe9
`(config-if)#channel-group 1 mode active`	Make it member port of po1
`(config)#interface xe10`	Enter Interface mode for xe10
`(config-if)#channel-group 1 mode active`	Make it member port of po1
`(config)#exit`	Exit from configuration mode

Spine 1

Spine node where all VTEPs are connected

Generic Configuration

`#configure terminal`	Enter Configure mode.
`(config)#qos enable`	Enabling QoS

Interface and Loopback Configuration

`(config)#interface lo`	Enter Interface mode for lo
`(config-if)#ip address 11.11.11.11/32 secondary`	Configure loopback IP address as 11.11.11.11 for Spine1
`(config-if)#exit`	Exit Interface mode and return to Configure mode.
`(config)#interface xe8`	Enter Interface mode for xe8
`(config-if)#ip address 10.10.10.2/24`	Configure IP address as 10.10.10.2 on network side of VTEP1
`(config-if)#exit`	Exit Interface mode and return to Configure mode.
`(config)#interface xe1`	Enter Interface mode for xe1
`(config-if)#ip address 30.30.30.2/24`	Configure IP address as 30.30.30.2 on network side of VTEP2
`(config-if)#exit`	Exit Interface mode and return to Configure mode.
`(config)#interface xe18`	Enter Interface mode for xe18
`(config-if)#ip address 50.50.50.2/24`	Configure IP address as 50.50.50.2 on network side of VTEP3
`(config-if)#exit`	Exit Interface mode and return to Configure mode.

OSPF configuration

`(config)#router ospf 100`	Enter into router OSPF mode
`(config-router)#ospf router-id 11.11.11.11`	Configure router-ID as 11.11.11.11 (lo IP address)
`(config-router)#network 11.11.11.11/32 area 0.0.0.0`	Add 11.11.11.11 (lo IP address) network into area 0
`(config-router)#network 10.10.10.0/24 area 0.0.0.0`	Add 10.10.10.0 (VTEP1) network into area 0
`(config-router)#network 30.30.30.0/24 area 0.0.0.0`	Add 30.30.30.0 (VTEP2) network into area 0
`(config-router)#network 50.50.50.0/24 area 0.0.0.0`	Add 50.50.50.0 (VTEP3) network into area 0
`(config-router)#bfd all-interfaces`	Enabling BFD on all OSPF interface for fast convergence
`(config-if)#exit`	Exit Interface mode and return to Configure mode.

Spine 2

Spine node where all VTEPs are connected

Generic configuration

`#configure terminal`	Enter Configure mode.
`(config)#qos enable`	Enabling QoS

Interface and loopback configuration

`(config)#interface lo`	Enter Interface mode for lo
`(config-if)#ip address 22.22.22.22/32 secondary`	Configure loopback IP address as 22.22.22.22 for Spine2
`(config-if)#exit`	Exit Interface mode and return to Configure mode.
`(config)#interface xe5`	Enter Interface mode for xe5
`(config-if)#ip address 20.20.20.2/24`	Configure IP address as 20.20.20.2 on network side of VTEP1
`(config-if)#exit`	Exit Interface mode and return to Configure mode.
`(config)#interface ce0`	Enter Interface mode for ce0
`(config-if)#ip address 40.40.40.2/24`	Configure IP address as 40.40.40.2 on network side of VTEP2
`(config-if)#exit`	Exit Interface mode and return to Configure mode.
`(config)#interface xe19`	Enter Interface mode for xe19
`(config-if)#ip address 60.60.60.2/24`	Configure IP address as 60.60.60.2 on network side of VTEP3
`(config-if)#exit`	Exit Interface mode and return to Configure mode.

OSPF configuration

`(config)#router ospf 100`	Enter into router OSPF mode
`(config-router)#ospf router-id 22.22.22.22`	Configure router-id as 11.11.11.11 (lo IP address)
`(config-router)#network 22.22.22.22/32 area 0.0.0.0`	Add 22.22.22.22 (lo IP address) network into area 0
`(config-router)#network 20.20.20.0/24 area 0.0.0.0`	Add 20.20.20.0 (VTEP1) network into area 0
`(config-router)#network 40.40.40.0/24 area 0.0.0.0`	Add 40.40.40.0 (VTEP2) network into area 0
`(config-router)#network 60.60.60.0/24 area 0.0.0.0`	Add 60.60.60.0 (VTEP3) network into area 0
`(config-router)#bfd all-interfaces`	Enabling BFD on all OSPF interface for fast convergence
`(config-if)#exit`	Exit Interface mode and return to Configure mode.

Static MAC-IP Advertise through Single Home and Multihomed VTEPs

Advertise static MAC IPv4 from MH1 and SH3.

MH1-VTEPs: VTEP1 & VTEP2- same MAC should be configured on both VTEPs under po access-port, configs should be symmetric between MH VTEPs

SH3-VTEP: VTEP3

VTEP1 (MH1)

`#configure terminal`	Enter Configure mode.
`(config)# nvo vxlan access-if port-vlan po1 1001`	Enter into VxLAN MH po1 access-port with VLAN 1001

(config-nvo-acc-if)#mac 0000.1111.1001 ip 11.11.10.1	Configure static MAC IP
(config-nvo-acc-if)#exit	Exit from VxLAN access-port config mode
(config)#exit	Exit from configuration mode

VTEP2 (MH1)

#configure terminal	Enter Configure mode.
(config)#nvo vxlan access-if port-vlan po1 1001	Enter into VxLAN MH po1 access-port with vlan 1001
(config-nvo-acc-if)# mac 0000.1111.1001 ip 11.11.10.1	Configure static MAC IP
(config-nvo-acc-if)#exit	Exit from VxLAN access-port config mode
(config)#exit	Exit from configuration mode

VTEP3 (SH)

#configure terminal	Enter Configure mode.
(config)# nvo vxlan access-if port-vlan xe48 1001	Enter into single-homed access-port - xe48 with VLAN 1001
(config-nvo-acc-if)#mac 0000.3333.1001 ip 11.11.10.2	Configure static MAC IP
(config-nvo-acc-if)#exit	Exit from VxLAN access-port config mode
(config)#exit	Exit from configuration mode

Validation

Verify MAC-table in MH VTEPs and Single Home VTEP, MAC will be advertised through ESI value which is advertised from VTEP1 and VTEP2 and VTEP IP from SH VTEP VTEP3.

Verify ARP-cache table in all VTEPs, VTEP1 and VTEP2 will learn VTEP3 IP.

Any ARP request comes for 11.11.10.2, VTEP1/VTEP2 will do proxy-ARP.

Dynamic MAC Advertise through Single Home and Multihomed VTEPs

Advertise 2 MAC's through CE1 connected IXIA, dynamic MAC entries and verify MAC-table in all VTEPs.

One MAC will be dynamic local in VTEP1 and same will be remote in VTEP2 and other be dynamic local in VTEP2 and same will be remote in VTEP1.

Both MAC's will be in remote in VTEP3.

Note:

- When VTEP1 tunnel goes down, then traffic from VTEP3 will use VTEP2 for forwarding. But Traffic from Switch to VTEP1 will be lost in VTEP1 itself.
- When DUT is rebooted, access-if will be in hold down state until ESI hold timer value expiry. After ESI hold timer expiry, access-if port will be up and started learning.
- MAC Hold timer will not be applicable on ESI interface, because of mass-withdraw requirement.
- A CE can connect to maximum two nodes for multihoming, more than two nodes in a multihoming group is not supported.
- All configuration (shutdown, disable learning, disable arp/nd cache, disable arp/nd flood, map vnid, qos profiles, encapsulation) on a multihomed access port should be same on both VTEPs sharing the ESI for multihoming functionalities to work properly.
- Multiple ESI values are supported on same VTEP.

CHAPTER 4 VXLAN Quality of Service Configuration

This chapter contains the configurations for VXLAN Quality of Service (QoS).

Overview

VXLAN enables multiple tenants to operate in a data center. Each tenant is assigned a priority group to prioritize their traffic. Cloud carriers want to use quality of service to differentiate different applications.

Data center networks are being increasingly used by telecommunications operators as well as by enterprises. Currently these networks are organized as one large Layer 2 network in a single building. In some cases, such a network is extended geographically using Virtual Local Area Network (VLAN) technologies as an even larger Layer 2 network connecting the virtual machines (VM), each with its own MAC address.

Multiple tenants might want their own isolated network domain. In a data center hosting multiple tenants, each tenant may independently assign MAC addresses and VLAN IDs and this might lead to duplication.

Cloud carriers wish to categorize the traffic based on the application such as voice, video, etc. Based on the type of the application different traffic classes may be identified and different priority levels can be assigned to each. To do so, quality of service marking is needed in VXLAN.

This chapter shows how to mark packet headers with the VXLAN tunnel end point (VTEP) when the frames are introduced by the virtual machines. The (re)marking /setting of QoS field DSCP/TOS in the VXLAN IP header is done with the two modes which are set globally.

Topology

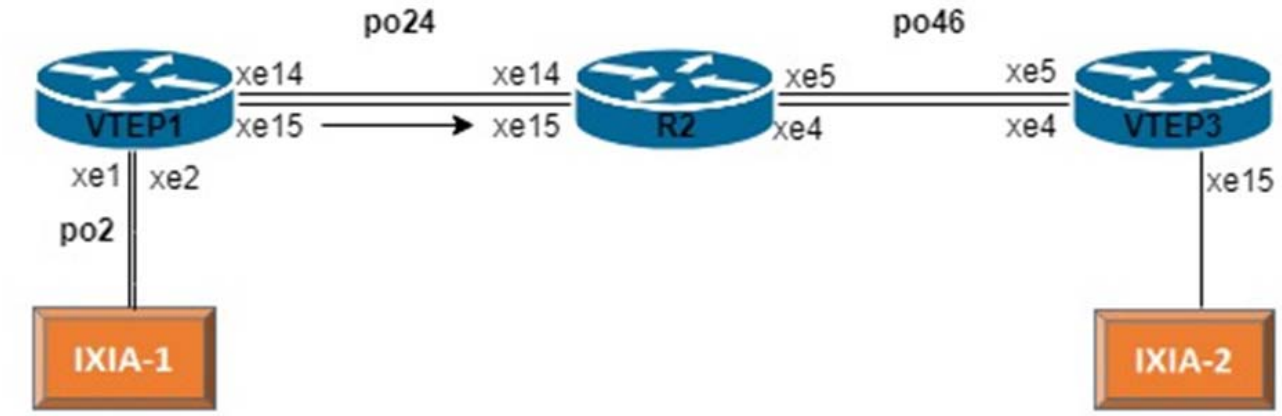

Figure 4-129: VXLAN QoS

COS-DSCP

RTR1/VTEP1

`VTEP1#configure terminal`	Enter Configure mode.
`VTEP1(config)#mac vrf vrf1`	Create mac routing/forwarding instance with vrf1 name and enter into vrf mode
`VTEP1(config-vrf)#rd 1.1.1.1:11`	Assign RD value
`VTEP1(config-vrf)#route-target both 10.10.10.10:100`	Assign route-target value for import/export
`VTEP1(config-vrf)#hardware-profile filter vxlan enable`	Enable hardware profile for vxlan
`VTEP1(config)#nvo vxlan enable`	Enable vxlan
`VTEP1(config)#qos enable`	Enable qos
`VTEP1(config)#qos profile cos-to-queue COS-QUE`	Create qos profile for mapping traffic towards tunnel from access-if.
`VTEP1(config-ingress-cos-map)#cos 1 queue 3`	Configure particular COS value to the queue value for configured profile.
`VTEP1(config-ingress-dscp-map)#qos profile queue-color-to-dscp QUE-DSCP`	Create qos profile for attaching in vxlan tunnel egress.
`VTEP1(config-egress-dscp-map)#queue 3 dscp 16`	Configure particular queue value to the dscp value for configured profile.
`VTEP1(config-egress-dscp-map)#interface po2`	Create a port channel po2
`VTEP1(config-if)#switchport`	Configure port as switchport
`VTEP1(config-if)#load-interval 30`	Set load-interval
`VTEP1(config-if)#interface po24`	Create a port channel po24
`VTEP1(config-if)#load-interval 30`	Configure port as switchport
`VTEP1(config-if)#ip address 24.1.1.1/30`	Set load-interval
`VTEP1(config-if)#interface lo`	Enter in to loopback interface
`VTEP1(config-if)#ip address 1.1.1.1/32 secondary`	Configure ip address
`VTEP1(config-if)#interface xe1`	Enter in to interface mode
`VTEP1(config-if)#channel-group 2 mode active`	Map to channel-group
`VTEP1(config-if)#interface xe2`	Enter in to interface mode
`VTEP1(config-if)#channel-group 2 mode active`	Map to channel-group
`VTEP1(config-if)#interface xe14`	Enter in to interface mode
`VTEP1(config-if)#channel-group 24 mode active`	Map to channel-group
`VTEP1(config-if)#interface xe15`	Enter in to interface mode
`VTEP1(config-if)#channel-group 24 mode active`	Map to channel-group
`VTEP1(config-if)#router ospf 1`	Create ospf instance
`VTEP1(config-router)#ospf router-id 1.1.1.1`	Configure ospf router-id

VTEP1(config-router)#network 1.1.1.1/32 area 0.0.0.0	Configure loopback network address in to ospf
VTEP1(config-router)#network 24.1.1.0/30 area 0.0.0.0	Configure network address in to ospf
VTEP1(config-router)#router bgp 100	Enter into Router BGP mode
VTEP1(config-router)#neighbor 6.6.6.6 remote-as 100	Specify a neighbor router with peer ip address and remote-as defined
VTEP1(config-router)#neighbor 6.6.6.6 update-source lo	Specify the neighbor to use loopback address as source
VTEP1(config-router)#address-family l2vpn evpn	Enter into l2vpn evpn address-family
VTEP1(config-router-af)#neighbor 6.6.6.6 activate	Activate the neighbor to address-family
VTEP1(config-router)#nvo vxlan vtep-ip-global 1.1.1.1	Configure Source vtep-ip-global configuration
VTEP1(config)#nvo vxlan tunnel qos-map-mode cos-dscp egress QUE-DSCP	Configure the mapping qos profile in to vxlan tunnel egress
VTEP1(config)#nvo vxlan id 1 in-gress-replication inner-vid-disabled	Create vnid 1 and disable inner-vid
VTEP1(config-nvo)#vxlan host-reachability-protocol evpn-bgp vrf1	Assign vrf for evpn-bgp to carry EVPN route
VTEP1(config-nvo)#nvo vxlan access-if port-vlan po2 1001	Create vxlan access-if with vlan 1001
VTEP1(config-nvo-acc-if)#no shutdown	No shut the vxlan access-if
VTEP1(config-nvo-acc-if)#map vnid 1	Map vnid to the vxlan access-if
VTEP1(config-nvo-acc-if)#map qos-profile cos-to-queue COS-QUE	Map qos profile for vxlan access-if ingress traffic from CE

RTR2

R2#configure terminal	Enter Configure mode.
R2(config)#interface po24	Create port channel
R2(config-if)#load-interval 30	Set load-interval
R2(config-if)#ip address 24.1.1.2/30	Assign ip address
R2(config-if)#interface po46	Create port channel
R2(config-if)#load-interval 30	Set load-interval
R2(config-if)#ip address 46.1.1.1/30	Assign ip address
R2(config-if)#interface lo	Enter in to loopback interface
R2(config-if)#ip address 4.4.4.4/32 secondary	Assign secondary ip address
R2(config-if)#interface xe4	Enter into interface mode
R2(config-if)#channel-group 46 mode active	Map port channel to the interface
R2(config-if)#interface xe5	Enter into interface mode
R2(config-if)#channel-group 46 mode active	Map port channel to the interface
R2(config-if)#interface xe14	Enter into interface mode
R2(config-if)#channel-group 24 mode active	Map port channel to the interface

`R2(config-if)#interface xe15`	Enter into interface mode
`R2(config-if)#channel-group 24 mode active`	Map port channel to the interface
`R2(config-if)#router ospf 1`	Create ospf instance
`R2(config-router)#ospf router-id 4.4.4.4`	Configure ospf router-id
`R2(config-router)#network 4.4.4.4/32 area 0.0.0.0`	Configure ospf network address with respective area
`R2(config-router)#network 24.1.1.0/30 area 0.0.0.0`	Configure ospf network address with respective area
`R2(config-router)#network 46.1.1.0/30 area 0.0.0.0`	Configure ospf network address with respective area

RTR3/VTEP2

`VTEP3#configure terminal`	Enter Configuration mode
`VTEP3(config)#mac vrf vrf1`	Create mac routing/forwarding instance with vrf1 name and enter into vrf mode
`VTEP3(config-vrf)#rd 6.6.6.6:11`	Assign RD value
`VTEP3(config-vrf)#route-target both 10.10.10.10:100`	Assign route-target value for import/export
`VTEP3(config-vrf)#hardware-profile filter vxlan enable`	Enable hardware profile vxlan
`VTEP3(config)#nvo vxlan enable`	Enable vxlan
`VTEP3(config)#qos enable`	Enable QOS
`VTEP3(config)#qos statistics`	Enable QOS statistics
`VTEP3(config-ingress-cos-map)#qos profile queue-color-to-cos QUE-COS`	Create qos profile for mapping incoming traffic from tunnel to access-if.
`VTEP3(config-egress-cos-map)#queue 4 cos 5`	Configure particular queue value to the cos value for configured profile.
`VTEP3(config-egress-cos-map)#qos profile dscp-to-queue DSCP-QUE`	Create qos profile for attaching in vxlan tunnel ingress.
`VTEP3(config-ingress-dscp-map)#dscp 16 queue 4`	Configure particular dscp value to the queue value for configured profile.
`VTEP3(config-egress-dscp-map)#interface po46`	Create port channel
`VTEP3(config-if)#load-interval 30`	Set load interval
`VTEP3(config-if)#ip address 46.1.1.2/30`	Assign ip address
`VTEP3(config-if)#interface lo`	Enter into loopback interface
`VTEP3(config-if)#ip address 6.6.6.6/32 secondary`	Assign secondary ip address
`VTEP3(config-if)#interface xe4`	Enter into interface mode
`VTEP3(config-if)#channel-group 46 mode active`	Map channel group into the interface
`VTEP3(config-if)#interface xe5`	Enter into interface mode
`VTEP3(config-if)#channel-group 46 mode active`	Map channel group into the interface
`VTEP3(config-if)#interface xe15`	Enter into interface mode

VTEP3(config-if)#switchport	Make interface as L2 port
VTEP3(config-if)#load-interval 30	Set load interval
VTEP3(config-if)#router ospf 1	Create ospf instance
VTEP3(config-router)#ospf router-id 6.6.6.6	Configure ospf router-id
VTEP3(config-router)#network 6.6.6.6/32 area 0.0.0.0	Configure ospf network address with respective area
VTEP3(config-router)#network 46.1.1.0/30 area 0.0.0.0	Configure ospf network address with respective area
VTEP3(config-router)#router bgp 100	Enter into Router BGP mode
VTEP3(config-router)#neighbor 1.1.1.1 remote-as 100	Specify a neighbor router with peer ip address and remote-as defined
VTEP3(config-router)#neighbor 1.1.1.1 update-source lo	Specify the neighbor to use loopback address as source
VTEP3(config-router)#address-family l2vpn evpn	Enter into l2vpn evpn address-family
VTEP3(config-router-af)#neighbor 1.1.1.1 activate	Activate the neighbor to address-family
VTEP3(config)#nvo vxlan vtep-ip-global 6.6.6.6	Configure Source vtep-ip-global configuration
VTEP3(config)#nvo vxlan tunnel qos-map-mode cos-dscp ingress DSCP-QUE	Configure the mapping qos profile in to vxlan tunnel ingress
VTEP3(config)#nvo vxlan id 1 in-gress-replication inner-vid-disabled	Create vnid 1 and disable inner-vid
VTEP3(config-nvo)#vxlan host-reachability-protocol evpn-bgp vrf1	Assign vrf for evpn-bgp to carry EVPN route
VTEP3(config-nvo)#nvo vxlan access-if port-vlan xe15 1000	Create vxlan access-if with vlan 1000
VTEP3(config-nvo-acc-if)#no shutdown	No shut the vxlan access-if
VTEP3(config-nvo-acc-if)#map vnid 1	Map vnid to the vxlan access-if
VTEP3(config-nvo-acc-if)#map qos-profile queue-color-to-cos QUE-COS	Map qos profile for vxlan access-if egress traffic to CE

CHAPTER 5 VXLAN Tunnel Over SVI

This chapter contains the configurations for VXLAN Tunnel Over SVI.

Overview

VxLAN EVPN solution is envisioned to simplify the topology and configurations in Data Centers (DC). In Data Centers, CLOS topology was used, which makes network side pure L3 and uses EBGP as IGP.

VxLAN solution is required for Service Providers (SP) as well to run few of the services or all services in their network over VxLAN. When they choose to run few services over VxLAN, then on the network side there will be a need to run VxLAN over SVI.

Topology

The Topology shown below contains the 3 VTEPS i.e VTEP1 ,VTEP2 and VTEP3 and 3 core nodes P1 ,P2 and P3. Vxlan tunnel will be established between VTEPS over SVI interfaces. OSPF as IGP will be running between VTEPS and the core node to provide the end to end connectivity. Switch is connected between host and VTEP-1, VTEP-2 via dynamic LAG.

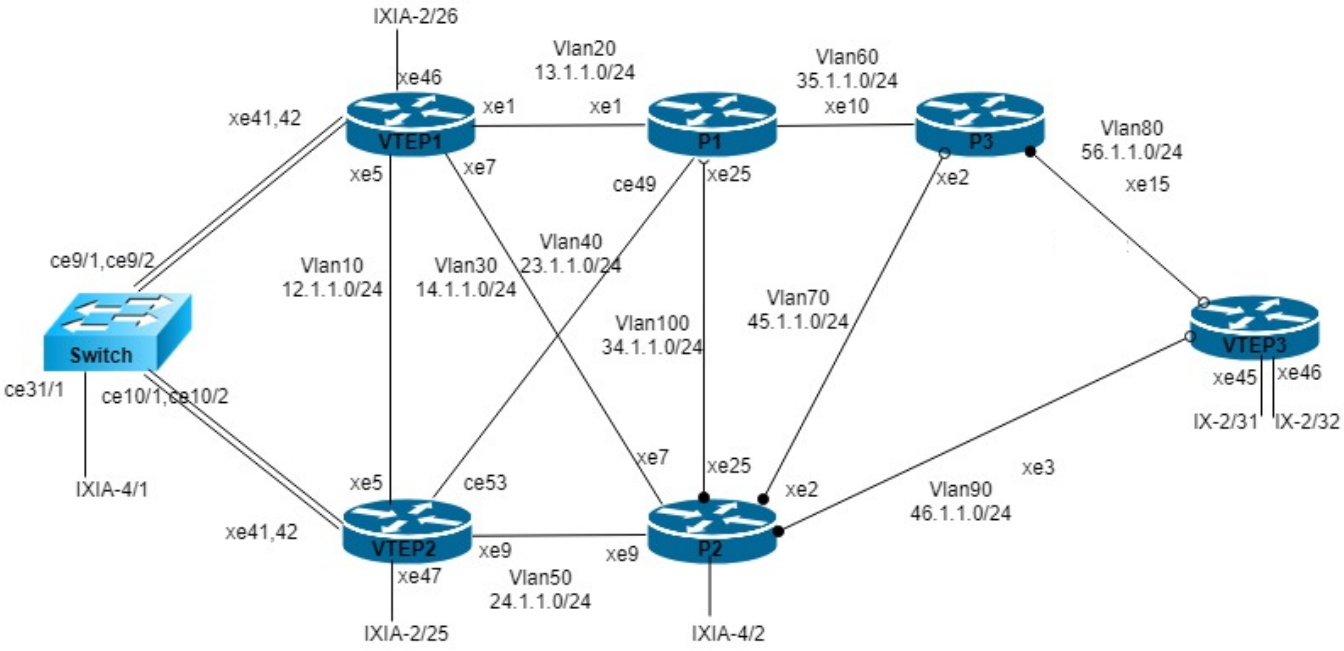

Figure 5-130: VXLAN over SVI

RTR1/VTEP1

`VTEP1#configure terminal`	Enter configuration terminal
`VTEP1(config)#hostname VTEP1`	Configure hostname

`VTEP1(config)#mac vrf vrf1`	Configure mac vrf vrf1
`VTEP1(config-vrf)# rd 1.1.1.1:11`	Configure RD for vrf1
`VTEP1(config-vrf)# route-target both 10.10.10.10:100`	Configure RT for vrf1
`VTEP1(config-vrf)#mac vrf vrf2`	Configure mac vrf vrf2
`VTEP1(config-vrf)# rd 1.1.1.1:12`	Configure RD for vrf2
`VTEP1(config-vrf)# route-target both 10.10.10.10:102`	Configure RT for vrf2
`VTEP1(config-vrf)#bfd interval 3 minrx 3 multiplier 3`	Configure bfd interval globally
`VTEP1(config)#hardware-profile filter egress-ipv4 enable`	Enable hardware filter for egress ipv4
`VTEP1(config)#hardware-profile filter vxlan enable`	Enable vxlan in hardware
`VTEP1(config)#nvo vxlan enable`	Enable vxlan
`VTEP1(config)#qos enable`	Enable qos
`VTEP1(config)#qos statistics`	Enable qos statistics
`VTEP1(config)#bridge 1 protocol ieee vlan-bridge`	Configure IEEE vlan bridge
`VTEP1(config)#no bridge 1 spanning-tree enable`	Disable spanning tree in bridge 1 globally
`VTEP1(config)#no igmp snooping`	Disable igmp snooping messages globally
`VTEP1(config)#vlan database`	Enter into the vlan database
`VTEP1(config-vlan)# vlan 10-200 bridge 1 state enable`	Configure vlan 10-200 and associate with bridge 1
`VTEP1(config-vlan)# vlan 4000 bridge 1 state enable`	Configure vlan 4000 and associate with bridge 1
`VTEP1(config-vlan)#interface po1`	Enter interface mode
`VTEP1(config-if)# switchport`	Set the interface as Layer2 port
`VTEP1(config-if)# load-interval 30`	Configure load period in multiple of 30 seconds
`VTEP1(config-if)#interface lo`	Enter lo interface mode
`VTEP1(config-if)# ip address 1.1.1.1/32 secondary`	Assign loopback ip
`VTEP1(config-if)#interface vlan1.10`	Specify interface vlan1.10 to be configured.
`VTEP1(config-if)# ip address 12.1.1.1/24`	Assign ip address
`VTEP1(config-if)# ip ospf cost 1`	Change ospf cost of the link
`VTEP1(config-if)#interface vlan1.20`	Specify interface vlan1.20 to be configured.
`VTEP1(config-if)# ip address 13.1.1.1/24`	Assign ip address
`VTEP1(config-if)# ip ospf cost 1`	Change ospf cost of the link
`VTEP1(config-if)#interface vlan1.30`	Specify interface vlan1.30 to be configured.
`VTEP1(config-if)# ip address 14.1.1.1/24`	Assign ip address
`VTEP1(config-if)# ip ospf cost 1`	Change ospf cost of the link
`VTEP1(config-if)#interface vlan1.110`	Specify interface vlan1.110 to be configured.
`VTEP1(config-if)# ip address 15.1.1.1/24`	Assign ip address

VTEP1(config-if)# ip ospf cost 1	Change ospf cost of the link
VTEP1(config-if)#interface xe1	Enter interface mode
VTEP1(config-if)# switchport	Set the interface as Layer2 port
VTEP1(config-if)# bridge-group 1 spanning-tree disable	Associate the interface with bridge group 1 and disable spanning tree
VTEP1(config-if)# switchport mode trunk	Set the switching characteristics of this interface to trunk mode.
VTEP1(config-if)# switchport trunk allowed vlan add 20,29	Enable VLAN's allowed on this interface.
VTEP1(config-if)# switchport trunk native vlan 29	Configure native vlan
VTEP1(config-if)# load-interval 30	Configure load period in multiple of 30 seconds
VTEP1(config-if)# spanning-tree edgeport	Set the port as an edge-port to enable rapid transitions
VTEP1(config-if)#interface xe5	Enter interface mode
VTEP1(config-if)# switchport	Set the interface as Layer2 port
VTEP1(config-if)# bridge-group 1 spanning-tree disable	Associate the interface with bridge group 1 and disable spanning tree
VTEP1(config-if)# switchport mode trunk	Set the switching characteristics of this interface to trunk mode.
VTEP1(config-if)# switchport trunk allowed vlan add 10-19	Enable VLAN's allowed on this interface.
VTEP1(config-if)# switchport trunk native vlan 19	Configure native vlan
VTEP1(config-if)# load-interval 30	Configure load period in multiple of 30 seconds
VTEP1(config-if)# spanning-tree edgeport	Set the port as an edge-port to enable rapid transitions
VTEP1(config-if)#interface xe7	Enter interface mode
VTEP1(config-if)# switchport	Set the interface as Layer2 port
VTEP1(config-if)# bridge-group 1 spanning-tree disable	Associate the interface with bridge group 1 and disable spanning tree
VTEP1(config-if)# switchport mode trunk	Set the switching characteristics of this interface to trunk mode.
VTEP1(config-if)# switchport trunk allowed vlan add 30,39	Enable VLAN's allowed on this interface.
VTEP1(config-if)# switchport trunk native vlan 39	Configure native vlan
VTEP1(config-if)# load-interval 30	Configure load period in multiple of 30 seconds
VTEP1(config-if)# spanning-tree edgeport	Set the port as an edge-port to enable rapid transitions
VTEP1(config-if)#interface xe19	Enter interface mode
VTEP1(config-if)# switchport	Set the interface as Layer2 port
VTEP1(config-if)# bridge-group 1 spanning-tree disable	Associate the interface with bridge group 1 and disable spanning tree
VTEP1(config-if)# switchport mode trunk	Set the switching characteristics of this interface to trunk mode.
VTEP1(config-if)# switchport trunk allowed vlan add 110-111	Enable VLAN's allowed on this interface.
VTEP1(config-if)# switchport trunk native vlan 111	Configure native vlan

`VTEP1(config-if)# load-interval 30`	Configure load period in multiple of 30 seconds
`VTEP1(config-if)# spanning-tree edgeport`	Set the port as an edge-port to enable rapid transitions
`VTEP1(config-if)#interface xe41`	Enter interface mode
`VTEP1(config-if)# channel-group 1 mode active`	Map this interface to po1
`VTEP1(config-if)#interface xe46`	Enter interface mode
`VTEP1(config-if)# switchport`	Map this interface to po1
`VTEP1(config-if)#router ospf 1`	Enter ospf configuration mode
`VTEP1(config-router)# ospf router-id 1.1.1.1`	Configure ospf router id
`VTEP1(config-router)# bfd all-interfaces`	Enable bfd in all ospf interfaces
`VTEP1(config-router)# network 1.1.1.1/32 area 0.0.0.0`	Define the Network on which OSPF runs and associate the area ID (area 0) with the interface.
`VTEP1(config-router)# network 12.1.1.0/24 area 0.0.0.0`	Define the Network on which OSPF runs and associate the area ID (area 0) with the interface.
`VTEP1(config-router)# network 13.1.1.0/24 area 0.0.0.0`	Define the Network on which OSPF runs and associate the area ID (area 0) with the interface.
`VTEP1(config-router)# network 14.1.1.0/24 area 0.0.0.0`	Define the Network on which OSPF runs and associate the area ID (area 0) with the interface.
`VTEP1(config-router)# network 15.1.1.0/24 area 0.0.0.0`	Define the Network on which OSPF runs and associate the area ID (area 0) with the interface.
`VTEP1(config-router)#router bgp 100`	Enter Router BGP mode and define the AS number 100.
`VTEP1(config-router)# network 1.1.1.1/32`	Add the lo network to bgp route
`VTEP1(config-router)# neighbor 2.2.2.2 remote-as 100`	Configure bgp remote-as 100 with neighbor IP
`VTEP1(config-router)# neighbor 2.2.2.2 update-source lo`	Define BGP neighbors, to update the source routes with lo
`VTEP1(config-router)# neighbor 6.6.6.6 remote-as 100`	Configure bgp remote-as 100 with neighbor IP
`VTEP1(config-router)# neighbor 6.6.6.6 update-source lo`	Define BGP neighbors, to update the source routes with lo
`VTEP1(config-router)# address-family l2vpn evpn`	Enter in to bgp l2vpn evpn address-family
`VTEP1(config-router-af)# neighbor 2.2.2.2 activate`	Activate neigbors
`VTEP1(config-router-af)# neighbor 6.6.6.6 activate`	Activate neigbors
`VTEP1(config-router-af)# exit-address-family`	Exit from bgp l2vpn evpn address-family
`VTEP1(config-router)#nvo vxlan vtep-ip-global 1.1.1.1`	Configure vxlan global ip
`VTEP1(config)#nvo vxlan id 1 ingress-replication inner-vid-disabled`	Create vnid 1
`VTEP1(config-nvo)# vxlan host-reachability-protocol evpn-bgp vrf1`	Associate vnid with evpn and vrf1
`VTEP1(config-nvo)#nvo vxlan id 1000 ingress-replication inner-vid-disabled`	Create vnid 1000
`VTEP1(config-nvo)# vxlan host-reachability-protocol evpn-bgp vrf2`	Associate vnid with evpn and vrf2

VTEP1(config-nvo)#nvo vxlan access-if port xe46	Create vxlan access port
VTEP1(config-nvo-acc-if)# no shutdown	Unshut the access interface
VTEP1(config-nvo-acc-if)# map vnid 1000	Map the vnid to access-if
VTEP1(config-nvo-acc-if)#nvo vxlan access-if port-vlan po1 1000	Create vxlan access port port-vlan
VTEP1(config-nvo-acc-if)# no shutdown	Unshut the access interface
VTEP1(config-nvo-acc-if)# map vnid 1	Map the vnid to access-if
VTEP1(config-nvo-acc-if)# mac 0000.1111.1111 ip 100.1.1.100	Configure static mac ip
VTEP1(config-nvo-acc-if)# mac 0000.1111.1112	Configure static mac
VTEP1(config-nvo-acc-if)# mac 0000.1111.1113	Configure static mac
VTEP1(config-nvo-acc-if)# mac 0000.1111.1114	Configure static mac
VTEP1(config-nvo-acc-if)# mac 0000.1111.1115	Configure static mac

VTEP2

VTEP2#configure terminal	Enter configuration terminal
VTEP2(config)#hostname VTEP2	Configure hostname
VTEP2(config)#mac vrf vrf1	Configure mac vrf vrf1
VTEP2(config-vrf)# rd 2.2.2.2:11	Configure RD for vrf1
VTEP2(config-vrf)# route-target both 10.10.10.10:100	Configure RT for vrf1
VTEP2(config-vrf)#mac vrf vrf2	Configure mac vrf vrf2
VTEP2(config-vrf)# rd 2.2.2.2:12	Configure RD for vrf2
VTEP2(config-vrf)# route-target both 10.10.10.10:102	Configure RT for vrf2
VTEP2(config-vrf)#load-balance enable	Enable load balancing
VTEP2(config)#load-balance l2 dest-mac src-mac	Enable load balance based on mac address
VTEP2(config)#load-balance ipv4 dest-ipv4 src-ipv4	Enable load balance based on ip address
VTEP2(config)#hardware-profile filter egress-ipv4 enable	Enable hardware filter for egress ipv4
VTEP2(config)#hardware-profile filter vxlan enable	Enable vxlan in hardware
VTEP2(config)#nvo vxlan enable	Enable vxlan
VTEP2(config)#qos enable	Enable qos
VTEP2(config)#qos statistics	Enable qos statistics
VTEP2(config)#bridge 1 protocol ieee vlan-bridge	Configure IEEE vlan bridge
VTEP2(config)#no bridge 1 spanning-tree enable	Disable spanning tree in bridge 1 globally
VTEP2(config)#vlan database	Enter into the vlan database

`VTEP2(config-vlan)# vlan 10-200 bridge 1 state enable`	Configure vlan 10-200 and associate with bridge 1
`VTEP2(config-vlan)#interface po2`	Enter interface mode
`VTEP2(config-if)# switchport`	Set the interface as Layer2 port
`VTEP2(config-if)# load-interval 30`	Configure load period in multiple of 30 seconds
`VTEP2(config-if)#interface ce53`	Enter interface mode
`VTEP2(config-if)# switchport`	Set the interface as Layer2 port
`VTEP2(config-if)# bridge-group 1 spanning-tree disable`	Associate the interface with bridge group 1 and disable spanning tree
`VTEP2(config-if)# switchport mode trunk`	Set the switching characteristics of this interface to trunk mode.
`VTEP2(config-if)# switchport trunk allowed vlan add 40,49`	Enable VLAN's allowed on this interface.
`VTEP2(config-if)# switchport trunk native vlan 49`	Configure native vlan
`VTEP2(config-if)# load-interval 30`	Configure load period in multiple of 30 seconds
`VTEP2(config-if)# spanning-tree edgeport`	Set the port as an edge-port to enable rapid transitions
`VTEP2(config-if)#interface lo`	Enter interface mode
`VTEP2(config-if)# ip address 2.2.2.2/32 secondary`	Configure loopback ip
`VTEP2(config-if)#interface vlan1.10`	Specify interface vlan1.10 to be configured.
`VTEP2(config-if)# ip address 12.1.1.2/24`	Assign ip address
`VTEP2(config-if)#interface vlan1.40`	Specify interface vlan1.40 to be configured.
`VTEP2(config-if)# ip address 23.1.1.1/24`	Assign ip address
`VTEP2(config-if)# ip ospf cost 1`	Change ospf cost of the link
`VTEP2(config-if)#interface vlan1.50`	Specify interface vlan1.50 to be configured.
`VTEP2(config-if)# ip address 24.1.1.1/24`	Assign ip address
`VTEP2(config-if)#interface xe5`	Enter interface mode
`VTEP2(config-if)# switchport`	Set the interface as Layer2 port
`VTEP2(config-if)# bridge-group 1 spanning-tree disable`	Associate the interface with bridge group 1 and disable spanning tree
`VTEP2(config-if)# switchport mode trunk`	Set the switching characteristics of this interface to trunk mode.
`VTEP2(config-if)# switchport trunk allowed vlan add 10-19`	Enable VLAN's allowed on this interface.
`VTEP2(config-if)# switchport trunk native vlan 19`	Configure native vlan
`VTEP2(config-if)# load-interval 30`	Configure load period in multiple of 30 seconds
`VTEP2(config-if)# spanning-tree edgeport`	Set the port as an edge-port to enable rapid transitions
`VTEP2(config-if)#interface xe9`	Enter interface mode
`VTEP2(config-if)# switchport`	Set the interface as Layer2 port
`VTEP2(config-if)# bridge-group 1 spanning-tree disable`	Associate the interface with bridge group 1 and disable spanning tree
`VTEP2(config-if)# switchport mode trunk`	Set the switching characteristics of this interface to trunk mode.

VTEP2(config-if)# switchport trunk allowed vlan add 50,59	Enable VLAN's allowed on this interface.
VTEP2(config-if)# switchport trunk native vlan 59	Configure native vlan
VTEP2(config-if)# load-interval 30	Configure load period in multiple of 30 seconds
VTEP2(config-if)# spanning-tree edgeport	Set the port as an edge-port to enable rapid transitions
VTEP2(config-if)#interface xe12	Enter interface mode
VTEP2(config-if)# switchport	Set the interface as Layer2 port
VTEP2(config-if)# bridge-group 1 spanning-tree disable	Associate the interface with bridge group 1 and disable spanning tree
VTEP2(config-if)# switchport mode trunk	Set the switching characteristics of this interface to trunk mode.
VTEP2(config-if)# switchport trunk allowed vlan add 50,59	Enable VLAN's allowed on this interface.
VTEP2(config-if)# switchport trunk native vlan 59	Configure native vlan
VTEP2(config-if)# load-interval 30	Configure load period in multiple of 30 seconds
VTEP2(config-if)# spanning-tree edgeport	Set the port as an edge-port to enable rapid transitions
VTEP2(config-if)#interface xe32	Enter interface mode
VTEP2(config-if)# switchport	Set the interface as Layer2 port
VTEP2(config-if)# bridge-group 1 spanning-tree disable	Associate the interface with bridge group 1 and disable spanning tree
VTEP2(config-if)# switchport mode trunk	Set the switching characteristics of this interface to trunk mode.
VTEP2(config-if)# switchport trunk allowed vlan add 160,169	Enable VLAN's allowed on this interface.
VTEP2(config-if)# switchport trunk native vlan 169	Configure native vlan
VTEP2(config-if)# load-interval 30	Configure load period in multiple of 30 seconds
VTEP2(config-if)# spanning-tree edgeport	Set the port as an edge-port to enable rapid transitions
VTEP2(config-if)#interface xe41	Enter interface mode
VTEP2(config-if)# channel-group 2 mode active	Map the interface to po2
VTEP2(config-if)#interface xe42	Enter interface mode
VTEP2(config-if)# channel-group 2 mode active	Map the interface to po2
VTEP2(config-if)#interface xe47	Enter interface mode
VTEP2(config-if)# switchport	Set the interface as Layer2 port
VTEP2(config-if)#router ospf 1	Enter ospf configuration mode
VTEP2(config-router)# ospf router-id 2.2.2.2	Configure ospf router id
VTEP2(config-router)# network 2.2.2.2/32 area 0.0.0.0	Enable bfd in all ospf interfaces
VTEP2(config-router)# network 12.1.1.0/24 area 0.0.0.0	Define the Network on which OSPF runs and associate the area ID (area 0) with the interface.
VTEP2(config-router)# network 23.1.1.0/24 area 0.0.0.0	Define the Network on which OSPF runs and associate the area ID (area 0) with the interface.

`VTEP2(config-router)# network 24.1.1.0/24 area 0.0.0.0`	Define the Network on which OSPF runs and associate the area ID (area 0) with the interface.
`VTEP2(config-router)# network 25.1.1.0/24 area 0.0.0.0`	Define the Network on which OSPF runs and associate the area ID (area 0) with the interface.
`VTEP2(config-router)#router bgp 100`	Enter Router BGP mode and define the AS number 100.
`VTEP2(config-router)# neighbor 1.1.1.1 remote-as 100`	Configure bgp remote-as 100 with neighbor IP
`VTEP2(config-router)# neighbor 1.1.1.1 update-source lo`	Define BGP neighbors, to update the source routes with lo
`VTEP2(config-router)# neighbor 6.6.6.6 remote-as 100`	Configure bgp remote-as 100 with neighbor IP
`VTEP2(config-router)# neighbor 6.6.6.6 update-source lo`	Define BGP neighbors, to update the source routes with lo
`VTEP2(config-router)# address-family l2vpn evpn`	Enter in to bgp l2vpn evpn address-family
`VTEP2(config-router-af)# neighbor 1.1.1.1 activate`	Activate neigbors
`VTEP2(config-router-af)# neighbor 6.6.6.6 activate`	Activate neigbors
`VTEP2(config-router-af)# exit-address-family`	Exit from bgp l2vpn evpn address-family
`VTEP2(config-router)#nvo vxlan vtep-ip-global 2.2.2.2`	Configure vxlan global ip
`VTEP2(config)#nvo vxlan id 1 ingress-replication inner-vid-disabled`	Create vnid 1
`VTEP2(config-nvo)# vxlan host-reachability-protocol evpn-bgp vrf1`	Associate vnid with evpn and vrf1
`VTEP2(config-nvo)#nvo vxlan id 1000 ingress-replication inner-vid-disabled`	Create vnid 1000
`VTEP2(config-nvo)# vxlan host-reachability-protocol evpn-bgp vrf2`	Associate vnid with evpn and vrf2
`VTEP2(config-nvo)#nvo vxlan access-if port xe47`	Create vxlan access port
`VTEP2(config-nvo-acc-if)# no shutdown`	Unshut the access interface
`VTEP2(config-nvo-acc-if)# map vnid 1`	Map the vnid to access-if
`VTEP2(config-nvo-acc-if)#nvo vxlan access-if port-vlan po2 2001`	Create vxlan access port
`VTEP2(config-nvo-acc-if)# no shutdown`	Unshut the access interface
`VTEP2(config-nvo-acc-if)# map vnid 1000`	Map the vnid to access-if
`VTEP2(config-nvo-acc-if)#nvo vxlan access-if port-vlan po2 2000`	Create vxlan access port
`VTEP2(config-nvo-acc-if)# no shutdown`	Unshut the access interface
`VTEP2(config-nvo-acc-if)# map vnid 1000`	Map the vnid to access-if
`VTEP2(config-nvo-acc-if)#end`	Exit from config mode

P1

`P1#configure terminal`	Enter configuration terminal
`P1(config)#hostname P1`	Configure hostname
`P1(config)#bfd interval 3 minrx 3 multiplier 3`	Configure bfd interval globally
`P1(config)#qos enable`	Enable qos
`P1(config)#bridge 1 protocol ieee vlan-bridge`	Configure IEEE vlan bridge
`P1(config)#no bridge 1 spanning-tree enable`	Disable spanning tree in bridge 1 globally
`P1(config)#no igmp snooping`	Disable igmp snooping messages globally
`P1(config)#vlan database`	Enter into the vlan database
`P1(config-vlan)# vlan 10-200 bridge 1 state enable`	Configure vlan 10-200 and associate with bridge 1
`P1(config-vlan)#interface ce49`	Enter interface mode
`P1(config-if)# switchport`	Set the interface as Layer2 port
`P1(config-if)# bridge-group 1 spanning-tree disable`	Associate the interface with bridge group 1 and disable spanning tree
`P1(config-if)# switchport mode trunk`	Set the switching characteristics of this interface to trunk mode.
`P1(config-if)# switchport trunk allowed vlan add 40,49`	Enable VLAN's allowed on this interface.
`P1(config-if)# switchport trunk native vlan 49`	Configure native vlan
`P1(config-if)# load-interval 30`	Configure load period in multiple of 30 seconds
`P1(config-if)# spanning-tree edgeport`	Set the port as an edge-port to enable rapid transitions
`P1(config-if)#interface lo`	Enter loopback interface mode
`P1(config-if)# ip address 3.3.3.3/32 secondary`	Assign loopback ip
`P1(config-if)#interface vlan1.20`	Specify interface vlan1.20 to be configured.
`P1(config-if)# ip address 13.1.1.2/24`	Assign ip address
`P1(config-if)# ip ospf cost 1`	Change ospf cost of the link
`P1(config-if)#interface vlan1.40`	Specify interface vlan1.40 to be configured.
`P1(config-if)# ip address 23.1.1.2/24`	Assign ip address
`P1(config-if)#interface vlan1.60`	Specify interface vlan1.60 to be configured.
`P1(config-if)# ip address 35.1.1.1/24`	Assign ip address
`P1(config-if)# ip ospf cost 1`	Change ospf cost of the link
`P1(config-if)#interface vlan1.100`	Specify interface vlan1.100 to be configured.
`P1(config-if)# ip address 34.1.1.1/24`	Assign ip address
`P1(config-if)# ip ospf cost 1`	Change ospf cost of the link
`P1(config-if)#interface vlan1.120`	Specify interface vlan1.120 to be configured.
`P1(config-if)# ip address 10.10.10.1/24`	Assign ip address
`P1(config-if)# ip ospf cost 1`	Change ospf cost of the link

`P1(config-if)#interface xe1`	Enter interface mode
`P1(config-if)# switchport`	Set the interface as Layer2 port
`P1(config-if)# bridge-group 1 spanning-tree disable`	Associate the interface with bridge group 1 and disable spanning tree
`P1(config-if)# switchport mode trunk`	Set the switching characteristics of this interface to trunk mode.
`P1(config-if)# switchport trunk allowed vlan add 20,29`	Enable VLAN's allowed on this interface.
`P1(config-if)# switchport trunk native vlan 29`	Configure native vlan
`P1(config-if)# load-interval 30`	Configure load period in multiple of 30 seconds
`P1(config-if)# mtu 1600`	Change the interface mtu value
`P1(config-if)# spanning-tree edgeport`	Set the port as an edge-port to enable rapid transitions
`P1(config-if)#interface xe10`	Enter interface mode
`P1(config-if)# switchport`	Set the interface as Layer2 port
`P1(config-if)# bridge-group 1 spanning-tree disable`	Associate the interface with bridge group 1 and disable spanning tree
`P1(config-if)# switchport mode trunk`	Set the switching characteristics of this interface to trunk mode.
`P1(config-if)# switchport trunk allowed vlan add 60,69`	Enable VLAN's allowed on this interface.
`P1(config-if)# switchport trunk native vlan 69`	Configure native vlan
`P1(config-if)# load-interval 30`	Configure load period in multiple of 30 seconds
`P1(config-if)# mtu 1600`	Change the interface mtu value
`P1(config-if)# spanning-tree edgeport`	Set the port as an edge-port to enable rapid transitions
`P1(config-if)#interface xe25`	Enter interface mode
`P1(config-if)# switchport`	Set the interface as Layer2 port
`P1(config-if)# bridge-group 1 spanning-tree disable`	Associate the interface with bridge group 1 and disable spanning tree
`P1(config-if)# switchport mode trunk`	Set the switching characteristics of this interface to trunk mode.
`P1(config-if)# switchport trunk allowed vlan add 100,109`	Enable VLAN's allowed on this interface.
`P1(config-if)# switchport trunk native vlan 109`	Configure native vlan
`P1(config-if)# load-interval 30`	Configure load period in multiple of 30 seconds
`P1(config-if)# spanning-tree edgeport`	Set the port as an edge-port to enable rapid transitions
`P1(config-if)#router ospf 1`	Enter ospf configuration mode
`P1(config-router)# ospf router-id 3.3.3.3`	Configure ospf router id
`P1(config-router)# bfd all-interfaces`	Enable bfd in all ospf interfaces
`P1(config-router)# network 3.3.3.3/32 area 0.0.0.0`	Define the Network on which OSPF runs and associate the area ID (area 0) with the interface.
`P1(config-router)# network 10.10.10.0/24 area 0.0.0.0`	Define the Network on which OSPF runs and associate the area ID (area 0) with the interface.

P1(config-router)# network 13.1.1.0/24 area 0.0.0.0	Define the Network on which OSPF runs and associate the area ID (area 0) with the interface.
P1(config-router)# network 23.1.1.0/24 area 0.0.0.0	Define the Network on which OSPF runs and associate the area ID (area 0) with the interface.
P1(config-router)# network 34.1.1.0/24 area 0.0.0.0	Define the Network on which OSPF runs and associate the area ID (area 0) with the interface.
P1(config-router)# network 35.1.1.0/24 area 0.0.0.0	Define the Network on which OSPF runs and associate the area ID (area 0) with the interface.
P1(config-router)#end	Exit from config mode

P2

P2#configure terminal	Enter configuration terminal

`VTEP3(config-vlan)#interface lo`	Configure vlan 10-200 and associate with bridge 1
`VTEP3(config-if)# ip address 6.6.6.6/32 secondary`	Enter lo interface mode
`VTEP3(config-if)#interface vlan1.80`	Assign loopback ip
`VTEP3(config-if)# ip address 56.1.1.2/24`	Specify interface vlan1.80 to be configured.
`VTEP3(config-if)# ip ospf cost 1`	Assign ip address
`VTEP3(config-if)#interface vlan1.90`	Change ospf cost of the link
`VTEP3(config-if)# ip address 46.1.1.2/24`	Specify interface vlan1.90 to be configured.
`VTEP3(config-if)# ip ospf cost 1`	Assign ip address
`VTEP3(config-if)#interface xe3`	Change ospf cost of the link
`VTEP3(config-if)# switchport`	Enter interface mode
`VTEP3(config-if)# bridge-group 1 spanning-tree disable`	Set the interface as Layer2 port

VTEP3(config-if)# switchport mode trunk	Associate the interface with bridge group 1 and disable spanning tree
VTEP3(config-if)# switchport trunk allowed vlan add 90,99	Set the switching characteristics of this interface to trunk mode.
VTEP3(config-if)# switchport trunk native vlan 99	Enable VLAN's allowed on this interface.
VTEP3(config-if)# load-interval 30	Configure native vlan
VTEP3(config-if)# spanning-tree edgeport	Configure load period in multiple of 30 seconds
VTEP3(config-if)#interface xe15	Set the port as an edge-port to enable rapid transitions
VTEP3(config-if)# bridge-group 1 spanning-tree disable	Enter interface mode
VTEP3(config-if)# switchport mode trunk	Associate the interface with bridge group 1 and disable spanning tree
VTEP3(config-if)# switchport trunk allowed vlan add 80,89	Set the switching characteristics of this interface to trunk mode.
VTEP3(config-if)# switchport trunk native vlan 89	Enable VLAN's allowed on this interface.
VTEP3(config-if)# load-interval 30	Configure native vlan
VTEP3(config-if)# mtu 1600	Configure load period in multiple of 30 seconds
VTEP3(config-if)# spanning-tree edgeport	Change interface mtu value
VTEP3(config-if)#interface xe33	Set the port as an edge-port to enable rapid transitions
VTEP3(config-if)# switchport	Enter interface mode
VTEP3(config-if)# bridge-group 1 spanning-tree disable	Set the interface as Layer2 port
VTEP3(config-if)# switchport mode trunk	Associate the interface with bridge group 1 and disable spanning tree
VTEP3(config-if)# switchport trunk allowed vlan add 120,125,165	Set the switching characteristics of this interface to trunk mode.
VTEP3(config-if)# switchport trunk native vlan 165	Enable VLAN's allowed on this interface.
VTEP3(config-if)# load-interval 30	Configure native vlan
VTEP3(config-if)# mtu 1600	Configure load period in multiple of 30 seconds
VTEP3(config-if)# spanning-tree edgeport	Change interface mtu value
VTEP3(config-if)#interface xe45	Set the port as an edge-port to enable rapid transitions
VTEP3(config-if)# switchport	Enter interface mode
VTEP3(config-if)# load-interval 30	Set the interface as Layer2 port
VTEP3(config-if)#interface xe46	Configure load period in multiple of 30 seconds
VTEP3(config-if)# switchport	Enter interface mode
VTEP3(config-if)# load-interval 30	Set the interface as Layer2 port
VTEP3(config-if)#router ospf 1	Configure load period in multiple of 30 seconds
VTEP3(config-router)# ospf router-id 6.6.6.6	Enter ospf configuration mode
VTEP3(config-router)# bfd all-interfaces	Configure ospf router id
VTEP3(config-router)# network 6.6.6.6/32 area 0.0.0.0	Enable bfd in all ospf interfaces

`VTEP3(config-router)# network 46.1.1.0/24 area 0.0.0.0`	Define the Network on which OSPF runs and associate the area ID (area 0) with the interface.
`VTEP3(config-router)# network 56.1.1.0/24 area 0.0.0.0`	Define the Network on which OSPF runs and associate the area ID (area 0) with the interface.
`VTEP3(config-router)#router bgp 100`	Define the Network on which OSPF runs and associate the area ID (area 0) with the interface.
`VTEP3(config-router)# neighbor 1.1.1.1 remote-as 100`	Enter Router BGP mode and define the AS number 100.
`VTEP3(config-router)# neighbor 1.1.1.1 update-source lo`	Configure bgp remote-as 100 with neighbor IP
`VTEP3(config-router)# neighbor 2.2.2.2 remote-as 100`	Define BGP neighbors, to update the source routes with lo
`VTEP3(config-router)# neighbor 2.2.2.2 update-source lo`	Configure bgp remote-as 100 with neighbor IP
`VTEP3(config-router)# address-family l2vpn evpn`	Define BGP neighbors, to update the source routes with lo
`VTEP3(config-router-af)# neighbor 1.1.1.1 activate`	Enter in to bgp l2vpn evpn address-family
`VTEP3(config-router-af)# neighbor 2.2.2.2 activate`	Activate neigbors
`VTEP3(config-router-af)# exit-address-family`	Activate neigbors
`VTEP3(config-router)#nvo vxlan vtep-ip-global 6.6.6.6`	Exit from bgp l2vpn evpn address-family
`VTEP3(config)#nvo vxlan id 1 ingress-replication inner-vid-disabled`	Configure vxlan global ip
`VTEP3(config-nvo)# vxlan host-reachability-protocol evpn-bgp vrf1`	Create vnid 1
`VTEP3(config-nvo)#nvo vxlan id 1000 ingress-replication inner-vid-disabled`	Associate vnid with evpn and vrf1
`VTEP3(config-nvo)# vxlan host-reachability-protocol evpn-bgp vrf2`	Create vnid 1000
`VTEP3(config-nvo)#nvo vxlan access-if port-vlan xe45 3001`	Associate vnid with evpn and vrf2
`VTEP3(config-nvo-acc-if)# no shutdown`	Create vxlan access port port-vlan
`VTEP3(config-nvo-acc-if)# map vnid 1`	Unshut the access interface
`VTEP3(config-nvo-acc-if)#nvo vxlan access-if port xe46`	Map the vnid to access-if
`VTEP3(config-nvo-acc-if)# no shutdown`	Create vxlan access port
`VTEP3(config-nvo-acc-if)# map vnid 1000`	Unshut the access interface
`VTEP3(config-nvo-acc-if)#end`	Map the vnid to access-if

Virtual eXtensible Local Area Network Command Reference

Contents

This document contains these chapters and appendices:

CHAPTER 1 VXLAN Commands

This chapter describes the VXLAN commands:

- show bgp l2vpn evpn
- show bgp l2vpn evpn summary
- show nvo vxlan
- show nvo vxlan access-if-config
- show nvo vxlan arp-cache
- show nvo vxlan counters access-port
- show nvo vxlan counters network-port
- show nvo vxlan mac-table
- show nvo vxlan static host state
- show nvo vxlan tunnel
- show running-config nvo vxlan
- show evpn multi-homing all
- show evpn multihoming-status
- show nvo vxlan route-count
- show nvo vxlan vni-name
- shutdown
- vxlan host-reachability-protocol evpn-bgp

arp-cache disable

Use this command to disable the ARP cache for MAC/IP.

When the ARP cache is disabled on a VxLAN access port, OcNOS does not reply to any ARP arriving on this port from the cache. OcNOS withdraws all MAC/IPs configured/learned on this access port and removes the MAC/IP entry for this access port from the local ARP cache.

OcNOS also makes sure that on withdrawing the MAC/IP route, the MAC does not become unknown. If all routes for this MAC are being withdrawn because of this command, then OcNOS advertises a MAC-only route. This is done so that the MAC does not become unknown and only the cache functionality becomes disabled.

See also `nvo vxlan max-cache-disable`.

Use the `no` form of this command to enable ARP cache for MAC/IP.

Note: On enabling the cache, an IP will be in conflict, then the cache enable will fail. The conflict has to be manually removed and then the cache enabled.

Command Syntax

```
arp-cache disable
no arp-cache disable
```

Parameters

None

Default

By default, the arp-cache option is enabled.

Command Mode

NVO access interface mode

Applicability

This command was introduced in OcNOS-SP version 4.0.

Example

```
#configure terminal
(config)#nvo vxlan access-if port-vlan xe1 2
(config-nvo-acc-if)#arp-cache disable
(config-nvo-acc-if)#exit
```

arp-nd flood-suppress

Use this command to completely restrict the flood of ARP/ND packets towards remote VTEPs or other access ports.

This command applies only when the ARP cache and ND cache are enabled. When the ARP cache is disabled, ARP flooding is not suppressed even if this command is given. When the ND cache is disabled, ND flooding is not disabled, even if this command is given.

Use the no form of this command to not restrict the flood of ARP/ND packets.

Command Syntax

```
arp-nd flood-suppress
no arp-nd flood-suppress
```

Parameters

None

Default

By default, the arp-nd flood-suppress option is disabled.

Command Mode

NVO access interface mode

Applicability

This command was introduced in OcNOS-SP version 4.0.

Example

```
#configure terminal
(config)#nvo vxlan access-if port-vlan xe1 2
(config-nvo-acc-if)#arp-nd flood-suppress
(config-nvo-acc-if)#exit
```

arp-nd refresh timer

Use this command to configure aging out the arp-cache and nd-cache entries for given time multiplied by 3 in seconds.

Use the no form of this command to remove the configuration.

Note: After this timer interval, it sends out ARP to revalidate and 3 times of this would lead to removal of the dynamic entry.

Command Syntax

```
nvo vxlan arp-nd refresh-timer <3-300000>
no nvo vxlan arp-nd refresh-timer
```

Parameters

<3-300000>	Refresh time in seconds

Command Mode

Configuration mode

Applicability

This command was introduced in OcNOS-SP version 4.0.

Example

```
#config mode
(config)#nvo vxlan arp-nd refresh-timer 100
(config)#no nvo vxlan arp-nd refresh-timer
```

clear mac address table dynamic vxlan

Use this command to clear dynamically learned MACs.

Command Syntax

```
clear mac address table dynamic vxlan
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#clear mac address table dynamic vxlan
```

clear nvo vxlan counters

Use this command to clear the counters of access ports or network ports.

Command Syntax

```
clear nvo vxlan counters((access-port (port IFNAME | port-vlan IFNAME VLAN_ID |
  all)) | (network-port (dst A.B.C.D | all)))
```

Parameters

`port`	Port
`IFNAME`	Interface name
`port-vlan`	VLAN port
`IFNAME`	Interface name
`VLAN_ID`	VLAN identifier
`A.B.C.D`	Tunnel destination IPv4 address
`all`	All access or network ports

Command Mode

Exec mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

Example for clearing a VLAN port counter:

```
#clear nvo vxlan counters access-port port-vlan xe1 2
```

Example for clearing all access port counters:

```
#clear nvo vxlan counters access-port all
```

Example for clearing network port counters:

```
#clear nvo vxlan counters network-port dst 1.1.1.1
```

Example for clearing all network port counters:

```
#clear nvo vxlan counters network-port all
```

clear nvo vxlan mac-stale-entries

Use this command to clear MAC entries that are in discard state in the forwarding database.

Command Syntax

```
clear nvo vxlan mac-stale-entries (vnid <1-16777215> |)
```

Parameters

<1-16777215>	VXLAN network identifier

Command Mode

Exec mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#clear nvo vxlan mac-stale-entries vnid 100
```

COS

Use this command to set a COS value and its direction.

Use the no form of this command to reset the COS value.

COS-DSCP mapping mode is configured globally.

Note: The COS value is not supported in configuring the access-port only.

Command Syntax

```
cos <0-7> (ingress|egress)
no cos <0-7> (ingress|egress)
```

Parameters

<0-7>	COS value
ingress	Ingress direction
egress	Egress direction

Default

By default, the COS priority is 0.

Command Mode

NVO access interface mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#configure terminal
(config)#nvo vxlan access-if port-vlan xe1 2
(config-nvo-acc-if)#cos 2 ingress
(config-nvo-acc-if)#cos 3 egress
(config)#exit
```

cos queue

Use this command to map a CoS to a queue.

Use the no form of this command to unmap a CoS from a queue.

Command Syntax

```
cos <0-7> queue <0-7>
no cos <0-7>
```

Parameters

<0-7>	COS value
<0-7>	Queue value

Default

By default, the COS priority is 0.

Command Mode

CoS queue profile mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#configure terminal
(config)#qos cos-queue-profile ingress 64
(config-cos-queue)#cos 2 queue 4
(config-cos-queue)#exit
```

description

Use this command to set a description for a port.

Use the no form of this command to remove the description for a port.

Command Syntax

```
description LINE
no description
```

Parameters

LINE	Maximum 32 characters describing this port.

Default

No default value is specified for description LINE commands.

Command Mode

NVO access interface mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#configure terminal
(config)#nvo vxlan access-if port-vlan xe1 2
(config-nvo-acc-if)#description member-port xe1 with vlan 2
(config-nvo-acc-if)#exit

#show running-config  nvo vxlan
!
nvo vxlan enable
!
nvo vxlan access-if port-vlan xe1 2
 description member-port xe1 with vlan 2
 no shutdown
```

dscp

Use this command to map an explicit DSCP value to an access-port.

Use the no form of this command to reset the DSCP value.

DSCP-DSCP mapping mode is configured globally.

Command Syntax

```
dscp <0-63> (ingress|egress)
no dscp <0-63> (ingress|egress)
```

Parameters

`<0-63>`	DSCP value
`ingress`	Ingress direction
`Egress`	Egress direction

Default

By default, the dscp priority is 0.

Command Mode

NVO access interface mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#configure terminal
(config)#nvo vxlan access-if port-vlan xe1 2
(config-nvo-acc-if)#dscp 24 ingress
(config-nvo-acc-if)#dscp 32 egress
(config-nvo-acc-if)#exit

#configure terminal
(config)#nvo vxlan access-if port xe1
(config-nvo-acc-if)#dscp 24 ingress
(config-nvo-acc-if)#dscp 32 egress
(config-nvo-acc-if)#exit
```

dscp queue

Use this command to map a DSCP value to a queue.

Use the no form of this command to unmap a DSCP value from a queue.

Command Syntax

```
dscp <0-63> queue <0-7>
no dscp <0-63>
```

Parameters

<0-63>	DSCP value
<0-7>	Queue

Default

By default, the dscp priority is 0.

Command Mode

DSCP queue configure mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#configure terminal
(config)#qos dscp-queue-profile ingress 128
(config-dscp-queue)#dscp 24 queue 4
(config-dscp-queue)#exit
```

dynamic-learning disable

Use this command to disable dynamic learning of MACs at the access port.

This command also disables dynamic learning of MAC/IP from ARP/ND messages received on this access port.

Use the no form of this command to enable dynamic learning of MACs at the access port.

Command Syntax

```
dynamic-learning disable
no dynamic-learning disable
```

Parameters

None

Default

By default, the dynamic-learning option is enabled.

Command Mode

NVO access interface mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#configure terminal
(config)#nvo vxlan access-if port-vlan xe1 2
(config-nvo-acc-if)#dynamic-learning disable
(config-nvo-acc-if)#exit
```

encapsulation

Use this command to assign a Tag Protocol Identifier (TPID) to an access port.

Use the no form of this command to set the default TPID (0x8100: IEEE 802.1Q VLAN-tagged frame) to an access port.

Command Syntax

```
dynamic-learning disable
no dynamic-learning disable
```

Parameters

TPID	Tag Protocol Identifier:
	Ox88A8: IEEE 802.1ad Provider Bridging
	Ox9100: IEEE 802.1Q VLAN-tagged frame with double tagging

Default

The encapsulation TPID default is 0X8100.

Command Mode

NVO access interface mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#configure terminal
(config)#nvo vxlan access-if port-vlan xe1 2
(config-nvo-acc-if)#dynamic-learning disable
(config-nvo-acc-if)#exit
```

evpn esi hold-time

Use this command to allow some time for the tunnels to come at the time of VxLAN initialization before making the ESI up. This avoids traffic to be black-holed when a new PE is added and connected to an already running CE for multihoming.

Use the no form of this command to make the ESI up immediately when configuring the access-if cli.

Command Syntax

```
evpn esi hold-time <10-300>
no evpn esi hold-time <10-300>
```

Parameters

<10-300>	Hold time in seconds

Default

The default value is 0.

Command Mode

Configuration Mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#configure terminal
(config)# evpn esi hold-time 100
(config)# exit
```

evpn multi-homed

Use this command to configure interfaces as multi-homed and configure esi-value for physical and static LAGs, and system-mac for dynamic LAGs.

Use the no parameter of this command to unconfigure multi-homing on an interface.

Command Syntax

```
evpn multi-homed (esi XX:XX:XX:XX:XX:XX:XX:XX:XX | system-mac (XX-XX-XX-XX-XX-
  XX|XX:XX:XX:XX:XX:XX|XXXX.XXXX.XXXX)
no evpn multi-homed (esi | system-mac)
```

Parameters

`XX:XX:XX:XX:XX:XX:XX:XX:XX`

ESI value in HH:HH:HH:HH:HH:HH:HH:HH:HH - 9 octet format

`XX-XX-XX-XX-XX-XX`

Host MAC address (Option 1)

`XX:XX:XX:XX:XX:XX`

Host MAC address (Option 2)

`XXXX.XXXX.XXXX`

Host MAC address (Option 3)

Default

The default value is 0.

Command Mode

Interface mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#configure terminal
(config)#interface xe1
(config)#evpn multi-homed esi 00:11:22:33:44:55:66:77:88
(config)#exit

configure terminal
(config)#interface po1
(config)#evpn multi-homed system-mac 0000.0000.1111
(config)#exit
```

evpn vxlan multihoming enable

Use this command to enable evpn vxlan multi-homing

Use the no form of this command to disable evpn vxlan multi-homing.

Note: You must restart the device after giving this command. If there are devices in the topology which have multi-homed CEs, then devices which do not have multi-homed CEs should also enable multihoming so that they can load share traffic to the multi-homed CEs.

Note: Before enabling multi-homing, configure the hardware-profiles:

- hardware-profile filter vxlan-mh
- hardware-profile filter with the `egress-ipv4` parameter

Command Syntax

```
evpn vxlan multihoming enable
no evpn vxlan multihoming enable
```

Parameters

None

Default

By default, multi-homing is disabled.

Command Mode

Configure mode

Applicability

This command was introduced before OcNOS version 1.3 and changed in OcNOS-SP version 4.0.

Example

```
#configure terminal
#(config)#evpn vxlan multihoming enable
#(config)#exit
```

hardware-profile filter vxlan

Use this command to configure hardware profile for nvo vxlan. This profile should be enabled before enabling VXLAN.

Note: You need to save the configuration and do a reboot after giving this command.

Command Syntax

```
hardware-profile filter vxlan enable
hardware-profile filter vxlan disable
```

Parameters

None

Command Mode

Configure mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
#config mode
(config)# hardware-profile filter vxlan enable
(config)# hardware-profile filter vxlan disable
```

hardware-profile filter vxlan-mh

Use this command to enable the hardware-profile for VXLAN multi-homing to successfully activate multi-homing in the hardware.

Before enabling EVPN multi-homing (evpn multi-homed command), give this command.

Before disabling the hardware-profile, disable EVPN multi-homing.

Note: You need to save the configuration and do a reboot after giving this command.

Use the `disable` form of this command to disable the configured hardware-profile.

Command Syntax

```
hardware-profile filter vxlan-mh enable
hardware-profile filter vxlan-mh disable
```

Parameters

None

Default

By default, the VXLAN multi-homing hardware-profile is disabled.

Command Mode

Configure mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
#configure terminal
#(config)#hardware-profile filter vxlan-mh enable
#(config)#hardware-profile filter vxlan-mh disable
#(config)#exit
```

mac

Use this command to associate a static MAC address and a static IPv4 address on an access interface.

Use the no form of this command to disassociate a static MAC address and an IPv4 address for an access interface.

Note: When a static host is configured on an access port which is in the down state, its state is Inactive.

Note: The same static mac configuration is not allowed on a different access port as then there will be a chance of conflict. However, if a dynamic packet is sent at another access port which is up and running with the same MAC, it learns as usual. As soon as the port on which the static MAC is configured comes up, static learning is given precedence and the dynamically learned MAC is moved to the port where it is configured statically.

Command Syntax

```
mac XXXX.XXXX.XXXX (| ip A.B.C.D)
no mac XXXX.XXXX.XXXX (| ip A.B.C.D)
```

Parameters

XXXX.XXXX.XXXX	Static MAC address. The following formats are supported:
	XX-XX-XX-XX-XX-XX Source MAC address (Option 1)
	XX:XX:XX:XX:XX:XX Source MAC address (Option 2)
	XXXX.XXXX.XXXX Source MAC address (Option 3)
A.B.C.D	Static IPv4 address.

Default

No default value is specified for mac command.

Command Mode

NVO access interface mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#configure terminal
(config)#nvo vxlan access-if port-vlan xe1 2
(config-nvo-acc-if)#mac 0000.0000.aaaa ip 10.10.10.1
(config-nvo-acc-if)#mac 0000.0000.aaa1
(config-nvo-acc-if)#exit
```

mac vrf

Use this command to create a MAC VRF to use in EVPN routes.

Limitation: If the VRF is linked with a VxLAN identifier, then it cannot be deleted and any route distinguisher or route target configured on it cannot be changed.

See also vxlan host-reachability-protocol evpn-bgp.

Use the no form of this command to delete the MAC VRF.

Command Syntax

```
mac vrf WORD
no mac vrf WORD
```

Parameter

WORD	MAC routing or forwarding instance name.

Command Mode

Configure mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#configure terminal
(config)#mac vrf vrf1

(config)#no mac vrf vrf1
```

mac-holdtime

Use this command to set the MAC hold time for a MAC/IP or MAC.

The feature holds the MAC in hardware until BGP has withdrawn from the neighbors. This helps to reduce flooding to other access ports.

This setting applies when the access port is shut down, the physical port on which the access port is down, or the access port is removed from the VNID using the no form of the map vnid command.

When the MAC hold time is configured as -1, then the MAC is not removed from the hardware and is also not withdrawn from EVPN BGP.

Use the no form of this command to remove the MAC hold time for the MAC/IP or MAC.

Note: When a MAC is moved to discard state, traffic to and from this MAC is discarded. This is applicable only on statically configured MAC/MAC-IPs.

Command Syntax

```
mac-holdtime <-1-300>
no mac-holdtime
```

Parameter

<-1-300>	MAC hold time in seconds. Specify -1 to "never expire".

Default

The default holdtime for mac is 3 seconds.

Command Mode

NVO mode and NVO_ACC_IF_MODE mode

Note: When configured in both modes, then the NVO_ACC_IF_MODE value takes preference for that access port.

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#configure terminal
(config)#nvo vxlan id 3 ingress-replication inner-vid-disabled
(config-nvo)#mac-holdtime -1
(config-nvo)#exit
```

map qos-profile

Use this command to map a QoS profile created with `qos cos-queue-profile` or `qos dscp-queue-profile` to an access port.

Use the no form of this command to unmap a QoS profile from an access port.

Command Syntax

```
map qos-profile (ingress|egress) <1-128>
no map qos-profile (ingress|egress)
```

Parameters

`ingress`	Ingress direction (access network)
`egress`	Egress direction (network access)
`<1-128>`	QoS profile identifier

Default

No default value is specified for map qos-profile command.

Command Mode

NVO access interface mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#configure terminal
(config)#nvo vxlan access-if port-vlan xe1 2
(config-nvo-acc-if)#map qos-profile ingress 64
(config-nvo-acc-if)#map qos-profile egress 100
(config-nvo-acc-if)#exit
```

map vnid

Use this command to map a tenant to an access-port.

Use the no form of this command to remove the tenant from an access-port.

See also nvo vxlan id.

Command Syntax

```
map vnid <1-16777215>
no map vnid <1-16777215>
```

Parameters

<1-16777215>	VxLAN network identifier

Default

No default value is specified for map vnid command.

Command Mode

NVO access interface mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#configure terminal
(config)#nvo vxlan access-if port-vlan xe1 2
(config-nvo-acc-if)#map vnid 100
(config-nvo-acc-if)#exit
```

nd-cache disable

Use this command to disable ND cache for MAC/IPv6.

When the ND cache is disabled on a VxLAN access port, OcNOS does not reply to any ND arriving on this port from the cache. OcNOS withdraws all MAC/IPs configured/learned on this access port and removes the MAC/IP entry for this access port from the local ND cache.

OcNOS also makes sure that on withdrawing the MAC/IP route, the MAC does not become unknown. If all routes for this MAC are being withdrawn because of this command, then OcNOS advertises a MAC-only route. This is done so that the MAC does not become unknown and only the cache functionality becomes disabled.

See also `arp-cache disable`.

Use the `no` form of this command to enable ND cache for MAC/IPv6.

Note: On enabling the cache, an IP will be in conflict, then the cache enable will fail. The conflict has to be manually removed and then the cache enabled.

Command Syntax

```
nd-cache disable
```

```
no nd-cache disable
```

Parameters

None

Default

By default, the nd-cache option is enabled.

Command Mode

NVO access interface mode

Applicability

This command was introduced in OcNOS-SP version 4.0.

Example

```
#configure terminal
(config)#nvo vxlan access-if port-vlan xe1 2
(config-nvo-acc-if)#nd-cache disable
(config-nvo-acc-if)#exit
```

nvo vxlan

Use this command to enable or disable VxLAN.

You must enable the VXLAN hardware profile with the hardware-profile filter vxlan command before enabling VxLAN.

Command Syntax

```
nvo vxlan (enable | disable)
```

Parameters

None

Default

By default, the VxLAN is disabled.

Command Mode

Configure mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#configure terminal
(config)#nvo vxlan enable

(config)#nvo vxlan disable
```

nvo vxlan access-if

Use this command to map a complete interface or a VLAN on an interface to identify the tenant traffic and to enter NVO access interface mode.

Use the no form of this command to unmap an interface or a VLAN.

Note: When a VxLAN access interface configured as a port VLAN is unconfigured, the traffic sent on the VLAN for that port hits some QoS policies which are set to not accept VLAN traffic on a port for which the VLAN is not configured. Such traffic is counted as VxLAN/ACL discards.

Command Syntax

```
nvo vxlan access-if (port IFNAME | port-vlan IFNAME VLAN_ID)
no nvo vxlan access-if (port IFNAME | port-vlan IFNAME VLAN_ID)
```

Parameters

port	A physical port.
IFNAME	Interface name (Physical/Static lag/Dynamic lag)
port-vlan	The physical port on which VLANs are configured
IFNAME	Interface name (Physical/Static lag/Dynamic lag)
VLAN_ID	VLAN identifier.

Default

By default, the nvo vxlan access-if option is port VLAN ID.

Command Mode

Configure mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#configure terminal
(config)#nvo vxlan access-if port-vlan xe1 2
(config-nvo-acc-if)#exit

#configure terminal
(config)#nvo vxlan access-if port xe1
(config-nvo-acc-if)#exit
```

nvo vxlan id

Use this command to add a tenant and the type of VPN. This command changes the mode to NVO mode.

Use no form of this command to unconfigure the VXLAN ID.

You must enable VXLAN with the nvo vxlan command before you give this command.

Command Syntax

```
nvo vxlan id <1-16777215> (multicast |) | (ingress-replication (| inner-vid-
  disabled)))
no nvo vxlan id <1-16777215> (multicast |) | (ingress-replication (| inner-vid-
  disabled)))
```

Parameters

`<1-16777215>`	VxLAN Network Identifier (VNID)
`multicast`	Point to multipoint.
`ingress-replication`	Use head end replication for forwarding BUM (Broadcast, Unknown Unicast, Multicast) traffic
`inner-vid-disabled`	Do not carry VID out of network port

Command Mode

Configure mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#configure terminal
(config)#nvo vxlan id 300 ingress-replication
(config-nvo)#exit

(config)#nvo vxlan id 200 ingress-replication inner-vid-disabled
(config-nvo)#exit
```

nvo vxlan mac-ageing-time

Use this command to set the dynamically learned MAC aging time.

Use the no form of this command to set the age out the MACs in hardware to its default (300 seconds).

Command Syntax

```
nvo vxlan mac-ageing-time <10-1000000>
no nvo vxlan mac-ageing-time
```

Parameters

<10-1000000>	Aging time in seconds

Default

The default age out time is 300 seconds.

Command Mode

Configure mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#configure terminal
(config)#nvo vxlan mac-ageing-time 10
```

nvo vxlan max-cache-disable

Use this command to configure the maximum number of ARP and ND cache disables on access ports configured with the port+VLAN options. This command does not limit the ARP and ND cache disables on access ports created with only the port option.

Use the no form of this command to set the maximum number of ARP and ND cache disables to its default (0).

Note: If any mac is in conflict when the max cache disable is being unconfigured, then the corresponding caches will not be enabled. This can be enabled after manually, removing the conflict. Caches where there is no conflict, are enabled.

Command Syntax

```
nvo vxlan max-cache-disable <1-200>
no nvo vxlan max-cache-disable
```

Parameters

<-1-200>	Number of ARP/ND cache disable allowed

Default

The default maximum number of ARP and ND cache disables is 0.

Command Mode

Configure mode

Applicability

This command was introduced in OcNOS-SP version 4.0.

Example

```
#configure terminal
(config)#nvo vxlan max-cache-disable 10
(config-nvo)#exit
```

nvo vxlan tunnel qos-map-mode

Use this command to configure QoS COS-DSCP or DSCP-DSCP mapping for a tunnel in the ingress or egress direction.

Use the no form of this command to remove QoS mapping for a tunnel.

Command Syntax

```
nvo vxlan tunnel qos-map-mode (cos-dscp|dscp-dscp) (ingress|egress) (<65-128>|)
nvo vxlan tunnel qos-map-mode (cos-dscp|dscp-dscp) (ingress|egress)
```

Parameters

`cos-dscp`	COS-to-DSCP mapping: the COS in packets entering on an access port is copied to the DSCP field of VXLAN header in packets exiting the tunnel
`dscp-dscp`	DSCP-to-DSCP mapping: the DSCP in packets entering on an access port is copied to the DSCP field of VXLAN header in packets exiting the tunnel
`ingress`	Ingress direction (access network)
`egress`	Egress direction (network access)
`<65-128>`	QoS profile ID

Default

No default value is specified for nvo vxlan tunnel qos-map-mode command.

Command Mode

Configuration mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#configure terminal
(config)#nvo vxlan tunnel qos-map-mode cos-dscp ingress
(config)#nvo vxlan tunnel qos-map-mode cos-dscp egress 128
(config)#exit

#configure terminal
(config)#nvo vxlan tunnel qos-map-mode dscp-dscp ingress
(config)#nvo vxlan tunnel qos-map-mode dscp-dscp egress 128
(config)#exit
```

nvo vxlan vtep-ip-global

Use this command to set the source IP address of the VxLAN tunnels.

Use the no form of this command to remove the source IP address of the VxLAN tunnels.

You must enable VXLAN with the nvo vxlan command before you give this command.

Command Syntax

```
nvo vxlan vtep-ip-global A.B.C.D
no nvo vxlan vtep-ip-global A.B.C.D
```

Parameters

A.B.C.D	Source VTEP IP address of the global configuration

Default

No default value is specified for nvo vxlan vtep-ip-global command.

Command Mode

NVO mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
(config-nvo)#nvo vxlan vtep-ip-global 10.10.11.1
```

qos cos-queue-profile

Use this command to create a QoS COS queue profile and enter COS queue profile mode.

Use the no form of this command to remove a COS queue profile.

Command Syntax

```
qos cos-queue-profile (ingress|egress) <1-64>
no qos cos-queue-profile <1-64>
```

Parameters

ingress	Ingress direction (access network)
egress	Egress direction (network access)
<1-128>	QoS profile identifier

Default

No default value is specified for qos cos-queue-profile command.

Command Mode

Configuration mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#configure terminal
(config)#qos cos-queue-profile ingress 64
(config-cos-queue)#exit
```

qos dscp-queue-profile

Use this command to configure create a QoS DSCP queue profile and enter DSCP queue profile mode.

Use the no form of this command to remove a QoS DSCP queue profile.

Command Syntax

```
qos dscp-queue-profile (ingress|egress) <65-128>
no qos dscp-queue-profile <65-128>
```

Parameters

ingress	Egress direction
egress	Ingress direction
<1-128>	QoS profile identifier

Default

No default value is specified for qos dscp-queue-profile command.

Command Mode

Configuration mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#configure terminal
(config)#qos dscp-queue-profile ingress 128
(config-dscp-queue)#exit
```

show bgp l2vpn evpn

Use this command to display details about Layer 2 Virtual Private Network (L2VPN) Ethernet Virtual Private Network (EVPN) routes.

Note: A BGP EVPN route update received for an unreachable IP address is also listed by this command and as a best route. This is because the next hop tracking feature is not supported for the EVPN address family. However, the tunnel to this IP address is shown in unresolved state by the show nvo vxlan tunnel output.

Command Syntax

```
show bgp l2vpn evpn ((vrf WORD)|(rd WORD)| time|)
show bgp l2vpn evpn mac-ip ((vrf WORD)|(rd WORD)|)
show bgp l2vpn evpn mcast
show bgp l2vpn evpn multihoming es-route <(rd WORD)|(vrf WORD)>
show bgp l2vpn evpn multihoming ethernet-ad-per-evi <(rd WORD)|(vrf WORD)>
show bgp l2vpn evpn multihoming ethernet-ad-per-es <(rd WORD)|(vrf WORD)>
```

Parameters

`vrf`	Virtual Routing and Forwarding instance
`WORD`	VRF name
`rd`	Route distinguisher
`WORD`	Route distinguisher: ASN:nn or IP:nn
`time`	Display learned time for EVPN routes
`mac-ip`	MAC/IP routes (EVPN type 2)
`mcast`	Multicast routes (EVPN type 3)

Command Mode

Exec mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#show bgp l2vpn evpn

BGP table version is 25, local router ID is 1.1.1.1
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,

Table 1-84 shows the status codes displayed at the start of a route entry.

Table 1-84: status codes

Status code	Description	Comments
s	suppressed	Whether the route is suppressed and is not advertised to neighbors.
d	damped	When the penalty of a flapping route exceeds the suppress limit, the route is damped and remains in a withdrawn state until its penalty decreases below the reuse limit.
h	history	When the penalty of a flapping route does not exceed the suppress limit, the route is not damped and BGP maintains a history of the flapping route.
*	valid	Whether the route is valid. When a route is not suppressed, damped, or present in the history, it is valid.
>	best	The selected route to be installed in the kernel routing table.
i	internal	The prefix was learned from an iBGP peer.
l	labeled	BGP Labeled Unicast advertises route information between inter region routers.

Table 1-85 shows the codes at the end of each route entry that indicate where the route originated.

Table 1-85: origin codes

Origin Code	Description	Comments
i	IGP	The route is from an Interior Gateway Protocol.
e	EGP	The route is from an Exterior Gateway Protocol.
?	incomplete	Origin not known. Typically, these are routes redistributed from an IGP.

Table 1-86 explains the fields for each route.

Table 1-86: route entry fields

Field	Description
RD	Route distinguisher: AS number or IP address.
VRF	Name of the VRF.
Network	EVPN route information. The route type indicates the type of routing information advertised by the EVPN control plane: 2 MAC/IP Route: Endpoint reachability information, including MAC and IP addresses of the endpoints. 3 Inclusive Multicast Route: Information about how to forward Broadcast, Unknown Unicast and Multicast (BUM) traffic. The other fields included depend on the route type: Type 2: [ESI]:[E-Tag]:[Length, Host MAC address]:[Length, Host IP address]:[Label/VNID] Type 3: [E-Tag]:[Length, PE IP address] ESI (Ethernet Segment Identifier): a unique non-zero identifier that identifies an Ethernet segment, which is a set of links that connects a network or device to one or more PEs. ESI 0 denotes a single-homed site. E-Tag (Ethernet tag): identifies a particular broadcast domain such as a VLAN or VNID in the VxLAN case. An EVPN instance consists of one or more broadcast domains. VNID (VXLAN network identifier): identifies Layer 2 segments and maintains Layer 2 isolation between the segments, allowing the addressing of up to 16 million logical networks in the same administrative domain. The status codes are explained in Table 1-84.
Next Hop	IP address of the nexthop for this route.
Metric	Multiple-Exit Discriminator (MED). If there are multiple paths to the same destination from a single routing protocol, then the multiple paths have the same administrative distance and the best path is selected based on this metric. The path with the lowest metric is selected as the optimal path and installed in the routing table.
LocPrf	This value is used only with iBGP sessions within the local autonomous system to determine if a route towards a destination is the “best” one. The path with the highest local preference is preferred.
Weight	This field applies only to routes within an individual router. If a route was learned from a peer, it has a default weight of 0. All routes generated by the local router have a weight of 32,768.

Table 1-86: route entry fields (Continued)

Field	Description
Path	The autonomous systems through which the prefix advertisement passed. The origin codes are explained in Table 1-85.
Peer	Neighbor address.
Total number of prefixes	The total number of prefixes listed.

show bgp l2vpn evpn summary

Use this command to display a summary of BGP EVPN neighbor status.

Command Syntax

```
show bgp l2vpn evpn summary
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#show bgp l2vpn evpn summary
BGP router identifier 1.1.1.1, local AS number 100
BGP table version is 17
1 BGP AS-PATH entries
0 BGP community entries

Neighbor                V   AS   MsgRcv    MsgSen TblVer   InQ   OutQ    Up/Down   State/PfxRcd     AD  MACIP  MCAST    ESI
8.8.8.8                 4   100  111        112      17      0      0  00:53:03              3      0      0      3      0
9.9.9.9                 4   100  110        110      17      0      0  00:52:10             15      0     13      2      0
13.13.13.13             4   100  132        109      17      0      0  00:51:57              4      0      2      2      0

Total number of neighbors 3

Total number of Established sessions 3
```

The start of the output shows:

- The BGP router identifier and the local router AS number.
- The BGP table version tracks the local BGP table version. Any time the BGP best path algorithm executes, the table version increments.
- BGP AS-PATH entry and community entries.

Table 1-87 explains the fields for each neighbor entry.

Table 1-87: neighbor fields

Field	Description
Neighbor	IP address of peer.
V	BGP version of peer.
AS	Autonomous system number of peer.
MsgRcvd	Messages received since the BGP connection was established.
MsgSent	Messages sent since the BGP connection was established.

Table 1-87: neighbor fields (Continued)

Field	Description
TblVer	Last version of the local router's BGP database advertised to the peer.
InQ	Received messages waiting in the input queue for further processing.
OutQ	Messages waiting in the output queue to be sent.
Up/Down	Connection up time in the interface.
State/PfxRcd	If the TCP session is up and the BGP peers have formed an adjacency, this field shows how many prefixes have been received from the remote neighbor. Other states: Idle: The local router has not allocated resources for the peer connection, so incoming connection requests are refused Idle (Admin): The peer has shut down Idle (PfxCt): Prefix overflow Idle (G-shut): Graceful shutdown Connect: BGP is waiting for the TCP connection to complete Active: the local router is trying to establish a TCP connection to the remote peer. You might see this if the local peer has been configured, but the remote peer is unreachable or has not been configured. OpenSent: BGP is waiting for an open message from its peer OpenConfirm: BGP received an open message from the peer and is now waiting for a keepalive or notification message. If BGP receives a keep alive message from the peer, the state changes to established. If the message is a notification, the state changes to idle. Established: BGP is ready to exchange update, notification, and keep alive messages with its peer Invalid: The session state is invalid.
AD	Number of EVPN type 1 Ethernet Auto-discovery routes: Only originated for multi-homed sites. Type 1 routes allow fast convergence where PE devices can change the next-hop adjacencies for all MAC addresses associated with a particular Ethernet Segment and aliasing where traffic can be balanced across multiple egress points
MACIP	Number of EVPN type 2 MAC/IP routes: Endpoint reachability information, including MAC and IP addresses of the endpoints.
MCAST	Number of EVPN type 3 Inclusive Multicast routes: Broadcast, Unknown Unicast and Multicast (BUM) traffic.
ESI	Number of EVPN type 4 Ethernet Segment Routes: Used in multi-homing for Designated Forwarder Election. The Designated Forwarder sends BUM traffic to the CE on a particular Ethernet Segment.

show nvo vxlan

Use this command to display VXLAN information.

Command Syntax

```
show nvo vxlan (vnid <1-16777215>|)
```

Parameters

<1-16777215>	VXLAN network identifier

Command Mode

Exec mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#sh nvo vxlan
VXLAN Information
================
   Codes: NW - Network Port
          AC - Access Port
         (u) - Untagged

Total number of entries are 6
```

Table 1-88 explains the fields in the output.

Table 1-88: VxLAN fields

Field	Description
VNID	VXLAN network identifier.
Type	NW - Network Port: VxLAN tunnel AC - Access Port: Host connection
Interface	Name of the Interface.
Vlan	VLAN identifier
Src-addr	Source address in the interface.
Dst-addr	Destination address in the interface.
Total number of entries	The total number of entries listed.

show nvo vxlan access-if-config

Use this command to display the current running configuration of the access interface.

Command Syntax

```
show nvo vxlan access-if-config (LINE|)
```

Parameters

LINE	Access port description

Command Mode

Exec mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#show nvo vxlan access-if-config
     nvo vxlan access-if port-vlan xe1 2
      map vnid 100
access-if-description member-port with xe1 as vlan 2
shutdown
mac 0000.0000.1111
mac 0000.0000.aaaa  ip 12.12.12.1
map qos-profile cos-to-queue ac_port_ingress
     !
     nvo vxlan access-if port-vlan po1 6
      no shutdown
      map vnid 100
     !
```

show nvo vxlan arp-cache

Use this command to display the ARP cache information.

Command Syntax

```
show nvo vxlan arp-cache (vnid <1-16777215>|)
```

Parameters

<1-16777215>	VXLAN network identifier

Command Mode

Exec mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#show nvo vxlan  arp-cache
VXLAN ARP-CACHE Information
===========================
VNID     Ip-Addr          Mac-Addr       Type        Age-Out    Retries-Left
_____________________________________________________________________________
10       12.12.12.2       0000.0000.2222 Static Local   ----
Total number of entries are 1
```

Table 1-89 explains the fields in the output.

Table 1-89: arp cache fields

Field	Description
VNID	VXLAN network identifier.
Ip-Addr	IP address of the vxlan.
Mac-Addr	Device MAC address.
Type	How a host learns a MAC/IP pair: Dynamic Local: Learned by data plane source learning Dynamic Remote: Learned by EVPN Type 2 (MAC/IP) routes Static Remote: Statically configured for remote; used only for static VxLAN, not with EVPN Static Local: Configured on local VTEP
Total number of entries	The total number of entries listed.

show nvo vxlan counters access-port

Use this command to display the receive and transmit counters of an access port.

Note: Due to a limitation in the hardware, the transmit packet counters includes the BUM traffic received on that port.

Note: To see the statistics, you must enable the hardware profile for the access-port with the hardware-profile filter command with the `ac-lif` parameter.

Note: All the expected packets might not be seen in the output of this command.

Command Syntax

```
show nvo vxlan counters access-port (port IFNAME | port-vlan IFNAME VLAN_ID | all)
```

Parameters

`IFNAME`	Access port name
`VLAN_ID`	VLAN identifier
`all`	All ports and VLANs

Command Mode

Exec mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#show nvo vxlan  counters access-port port-vlan xe13 10

Data packets:
   *If ARP/ND cache is enabled, TX doesn't count ARP/ND replies
 from  ARP/ND cache and ARP/ND forwarded after uplifting to
 the control plane.
   RX:  packets  : 2774939
        bytes    : 210553516
   TX:  packets  : 4322274
        bytes    : 326026474

Control Packets:
 *ARP/ND uplifted and sent/replied from control plane:
  Rx Vxlan Arp discard count           : 0
  Rx Vxlan Nd discard count            : 0
  Tx Vxlan Arp discard count           : 0
  Tx Vxlan Nd discard count            : 0
  Rx Vxlan Arp Request count           : 0
  Tx Vxlan Arp Request count           : 0
  Rx Vxlan Arp Reply count             : 5
  Tx Vxlan Arp Reply count             : 1
  Rx Vxlan Neighbor Solicitation count : 0
  Tx Vxlan Neighbor Solicitation count : 0
  Rx Vxlan Neighbor Advertisement count: 3
  Tx Vxlan Neighbor Advertisement count: 0
```

Table 1-90 explains the fields in the output.

Table 1-90: access port counters

Field	Description
RX: packets	Number of packets received on an access-interface.
RX: bytes	Number of bytes received.
TX: packets	Number of packets transmitted.
TX: bytes	Number of bytes transmitted.
Rx Vxlan Nd discard count	Number of discarded ND that is received from neighbor.
Tx Vxlan Arp discard count	Number of discarded Arp that is transmitted to peer.
Tx Vxlan Nd discard count	Number of discarded ND that is transmitted to peer.
Rx Vxlan Arp Request count	Number of request ARP that is received from neighbor.
Tx Vxlan Arp Request count	Number of request ARP that is transmitted to peer.
Rx Vxlan Arp Reply count	Number of replied ARP that is received from neighbor.
Tx Vxlan Arp Reply count	Number of replied ARP which is transmitted to peer.
Rx Vxlan Neighbor Solicitation count	Number of request ND that is received from neighbor.
Tx Vxlan Neighbor Solicitation count	Number of replied ND that is received from neighbor.
Rx Vxlan Neighbor Advertisement count	Number of Neighbor Advertisement that is received from neighbor.
Tx Vxlan Neighbor Advertisement count	Number of Neighbor Advertisement which is transmitted to peer.

show nvo vxlan counters network-port

Use this command to display the receive and transmit counters of a network port including ARP, ND and GARP counters.

Command Syntax

```
show nvo vxlan counters network-port (dst A.B.C.D | ALL)
```

Parameters

A.B.C.D	Tunnel IPv4 address
ALL	All addresses

Command Mode

Exec mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#show nvo vxlan counters network-port dst 2.2.2.2

Data packets:
  *If ARP/ND cache is enabled, TX doesn't count ARP/ND replies
from  ARP/ND cache and ARP/ND forwarded after uplifting to
the control plane.
  RX:  packets  : 0
       bytes    : 0
  TX:  packets  : 3570006
       bytes    : 406980684

Control Packets:
*ARP/ND uplifted and sent/replied from control plane:
 TX VXLAN ARP discard count           : 0
 TX VXLAN ND discard count            : 0
 Tx Vxlan ARP Request count           : 0
 Tx Vxlan ARP Reply count             : 0
 Tx Vxlan Neighbor Solicitation count : 0
 Tx Vxlan Neighbor Advertisement count: 0
```

Table 1-91 explains the each network entry fields.

Table 1-91: show nvo vxlan counters network-port output fields

Field	Description
RX: packets	Number of hello packets received from neighbor.
RX: bytes	Number of hello packets received from neighbor in bytes received.

Table 1-91: show nvo vxlan counters network-port output fields (Continued)

Field	Description
TX: packets	Number of hello packets transmitted to neighbor.
TX: bytes	Number of hello packets transmitted to neighbor in bytes transmitted.
Tx Vxlan Arp discard count	Number of discarded Arp that is transmitted to peer.
Tx Vxlan Nd discard count	Number of discarded ND that is transmitted to peer.
Tx Vxlan Arp Request count	Number of request ARP that is transmitted to peer.
Tx Vxlan Arp Reply count	Number of replied ARP which is transmitted to peer.
Tx Vxlan Neighbor Solicitation count	Number of replied ND that is received from neighbor.
Tx Vxlan Neighbor Advertisement count	Number of Neighbor Advertisement which is transmitted to peer.

show nvo vxlan mac-table

Use this command to display the host MAC address table. Use the hardware option to see the ageout time for the dynamically learn macs.

Command Syntax

```
show nvo vxlan mac-table (vnid <1-16777215>|) (summary | hardware|)
```

Parameters

<1-16777215>	VXLAN network identifier
summary	Display a count of MAC addresses
hardware	Display hardware information

Command Mode

Exec mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#show nvo vxlan mac-table

```

Table 1-92 explains the fields in the output.

Table 1-92: MAC table fields

Field	Description
VNID	VXLAN network identifier
Interface	Interface name
VlanId	VLAN identifier
Mac-Addr	MAC address
VTEP-Ip	VTEP identifier
Type	How a host learns a MAC/IP pair: Dynamic Remote: Learned by EVPN Type 2 (MAC/IP) routes Static Remote: Statically configured for remote; used only for static VxLAN, not with EVPN Static Local: Configured on local VTEP Dynamic Local: Learned by data plane source learning
Status	Max Move conflict: When a MAC has moved too many times (5 or more times in 180 seconds). This is according to the procedures defined in RFC 7432, Section 15.1. Discard: If a MAC hold time is configured, then if the VxLAN access port goes down (admin or operational), the MAC is moved to the discard state for the period of the hold time. The MAC is also moved to the discard state if the VNID is unmapped from the port. In dynamically learned cases, the MAC is also moved to discard when learning is disabled.
Time-out	Age timeout for dynamically learned MACs.
AccessPortDesc	Access port description.
Total number of entries	The total number of entries listed.

show nvo vxlan static host state

Use this command to display the state of the host which is configured statically.

Command Syntax

```
show nvo vxlan static host state
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#show nvo vxlan  static host state
VXLAN Static Host Information
=============================
   Codes: NW - Network Port
          AC - Access Port
         (u) - Untagged

Total number of entries are 5
```

Table 1-93 explains the output fields.

Table 1-93: Static host fields

Field	Description
VNID	VXLAN network identifier
Ifname	Interface name
Vlan	VLAN name
Ip-Addr	IP address

Table 1-93: Static host fields

Field	Description
Mac-Addr	MAC address
Status	Status of the MAC/IP on the host: Conflict: When a MAC/IP was configured, the conflict was not known as the VNID was not mapped to the access port. After the VNID is mapped, if the same MAC/IP is present statically on some other port on the same VNID, then it is in conflict state. Learnt Conflict: When a MAC/IP was configured, the conflict was not known. However, it is now in conflict because the same MAC/IP is configured on an access port on VTEP1 and on an access port on VTEP2. Because the BGP session/tunnel was not up, the MAC/IP was not known to the other VTEP and the configuration was allowed. When the BGP session/tunnel comes up and it finds such a conflicted route, it marks the state as Learnt Conflict. Inactive: Configured but not operating, such as when the port is not mapped to any VNID. The port is down and the ARP/ND cache is disabled. Active: Operating host MAC/IP.

show nvo vxlan tunnel

Use this command to view the source, destination, and status of the VxLAN tunnel entries.

Command Syntax

```
show nvo vxlan tunnel
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

The following is a sample output of the `show nvo vxlan tunnel` command.

```
#show nvo vxlan tunnel
VXLAN Network tunnel Entries
 Source Destination      Status Up/Down Update
================================================
1.1.1.1 2.2.2.2          Installed 00:00:20 00:00:20
Total number of entries are 1
```

Table 1-94 explains the output fields.

Table 1-94: VxLAN tunnel fields

Field	Description
Source	Tunnel source IP address.
Destination	Tunnel destination IP address.
Status	Installed: Tunnel Installed in the hardware and operating. Resolved: Tunnel destination IP is reachable, but VxLAN tunnel not installed in hardware. Therefore, not operating. Unresolved: Tunnel destination IP not reachable because L3 route is down.
Up/Down	When the tunnel came up or went down
Update	When the tunnel was last updated
Total number of entries	The total number of entries listed.

show running-config nvo vxlan

Use this command to display the current running configuration of VxLANs.

Command Syntax

```
show running-config nvo vxlan
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced in a version before OcNOS version 1.3.

Example

```
#sh running-config  nvo vxlan
!
evpn vxlan multihoming enable
!
evpn esi hold-time 100
!
nvo vxlan enable
!
nvo vxlan vtep-ip-global 2.2.2.2
!
nvo vxlan mac-ageing-time 10
!
nvo vxlan id 10 ingress-replication inner-vid-disabled

 no shutdown
 map vnid 10
!
```

show evpn multi-homing all

Use this command to display the multi-homed VTEP details.

Command Syntax

```
show evpn multi-homing all
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#show evpn multi-homing all
ESI                             Access-IF    PE-IP-ADDRESS
============================================================
00:00:11:22:33:44:55:66:77:88  ce21/1       1.1.1.1
00:00:11:22:33:44:55:66:77:88  ----         2.2.2.2
Total number of entries are 2
```

Table 1-95 explains the output fields.

Table 1-95: show evpn multi-homing all output details

Field	Description
ESI	An Ethernet segment has an unique nonzero identifier, called the Ethernet segment identifier (ESI). The ESI is encoded as a 10-octet integer that identifies this segment. When manually configuring an ESI value, the most significant octet, known as the type byte, must be 00. When a single-homed CE device is attached to an Ethernet segment, the entire ESI value is zero.
Access-IF	Map the access port ce21/1 for evpn.
PE-IP-ADDRESS	Address of the provider edge router in the interface.

show evpn multihoming-status

Use this command to display the status of multihoming on a VTEP.

Command Syntax

```
show evpn multihoming-status
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#show evpn multihoming-status
Multihoming is ACTIVE in Hardware
```

show nvo vxlan route-count

Use this command to display the VXLAN active route (MAC-IP and MAC-only) count information.

Command Syntax

```
show nvo vxlan route-count (|vnid <1-16777215>)
```

Parameters

<1-16777215>	Range supported for VNID

Command Mode

Exec mode

Applicability

This command was introduced before OcNOS version 1.3 and modified to include the GW-IPv4, and Prefix IPv4 in OcNOS version 1.3.5.

Example

```
#show nvo vxlan  route-count
VXLAN Active route count information
====================================
Max route count   : 32768
Active route count: 0

-------------------------------------------
 VNID     Total    MACONLY  MACIPv4  MACIPv6
-------------------------------------------
 100      0        0        0        0
 10       0        0        1        0

Total number of entries are 2
```

Table 1-96 explains the output fields.

Table 1-96: show nvo vxlan route-count output details

Field	Description
Max route count	Maximum number of route count in vxlan.
Active route count	Number of active route count in the interface.
VNID	VNID is used to identify Layer 2 segments and to maintain Layer 2 isolation between the segments.
Total	Total number of entries for the interface.
MACONLY	The MAC-only route for the local interface appears in the VXLAN instance route table.
MACIPv4	IPv4 media access control (MAC) address for a default virtual gateway.
MACIPv6	IPv6 media access control (MAC) address for a default virtual gateway.

show nvo vxlan vni-name

Use this command to display the vxlan results based on vni-name.

Command Syntax

```
show nvo vxlan vni-name (WORD)
```

Parameters

WORD	VXLAN id name

Command Mode

Exec mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#show nvo vxlan vni-name SITEA-PRO
VXLAN Information

```

shutdown

Use this command to administratively shut down an NVO access interface.

Use the no form of this command to start an NVO access interface.

Command Syntax

```
shutdown
no shutdown
```

Parameters

None

Default

The NVO access interface is running by default.

Command Mode

NVO access interface mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#configure terminal
(config)#nvo vxlan access-if port-vlan xe1 2
(config-nvo-acc-if)#shutdown
(config-nvo-acc-if)#exit
```

vxlan host-reachability-protocol evpn-bgp

Use this command to set the host reachable protocol to Ethernet-VPN over BGP. This defines BGP as the mechanism for host reachability advertisement.

Use use the no form of this command to remove Ethernet-VPN as the host reachable protocol.

Command Syntax

```
vxlan host-reachability-protocol evpn-bgp NAME
no vxlan host-reachability-protocol evpn-bgp
```

Parameters

NAME	Name of the VRF to carry VNID routes

Command Mode

NVO mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
(config)#nvo vxlan id 3 ingress-replication inner-vid-disabled
(config-nvo)#vxlan host-reachability-protocol evpn-bgp Blue
```

CHAPTER 2 VXLAN Quality of Service Commands

This chapter describes the VXLAN commands for QoS (Quality of Service):

clear nvo vxlan tunnels

Use this command to clear the nvo vxlan tunnels to re-establish the tunnel after mapping/un-mapping the QoS profile to vxlan tunnel.

Command Syntax

```
clear nvo vxlan tunnels
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
#clear nvo vxlan  tunnels
```

cos queue

Use this command to configure user defined mapping for cos and queue.

Use the no form of this command to remove the mapping.

Command Syntax

```
cos <0-7> queue <0-7>
no cos <0-7>
```

Parameters

cos	COS
queue	Queue number

Default

By default, the VXLAN multi-homing hardware-profile is disabled.

Command Mode

QoS config mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
(config)#qos profile cos-to-queue ac_port_ingress
(config-ingress-cos-map)#cos 1 queue 7
(config-ingress-cos-map)#no cos  1
```

dscp queue

Use this command to configure user defined mapping for DSCP to queue. This will be mapped with nvo VXLAN tunnel of remote VTEP.

Use the no form of this command to delete the mapping.

Command Syntax

```
dscp <0-63> queue <0-7>
no dscp <0-63>
```

Parameters

<0-63>	DSCP
<0-7>	Queue number

Command Mode

Ingress-dscp-map mode

Default

Default queue and cos value is one-one default mapping if it is not configured.

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
(config)#qos profile dscp-to-queue nw_profile
(config-ingress-dscp-map)#dscp 50 queue 1
(config-ingress-dscp-map)#no dscp 50
```

map qos-profile cos-to-queue

Use this command to map the cos-to-queue profile to vxlan access port on the local VTEP.

Use the no form of the command to remove the mapping.

Command Syntax

```
map qos-profile cos-to-queue NAME
```

Parameters

NAME	QoS profile name for access port mapping

Default

None

Command Mode

NVO mode

Applicability

This command was introduced before OcNOS-SP version 1.0.

Example

```
(config)#nvo vxlan access-if port-vlan xe1 10
(config-nvo-acc-if)#map qos-profile cos-to-queue ac_port_ingress
(config-nvo-acc-if)#no map qos-profile cos-to-queue ac_port_ingress
```

map qos-profile queue-color-to-cos

Use this command to map the queue-color-to-cos profile to vxlan access port on the remote VTEP.

Use the no form of the command to remove the mapping.

Command Syntax

```
map qos-profile queue-color-to-cos NAME
```

Parameters

NAME	QoS profile name for access port mapping

Default

None

Command Mode

NVO mode

Applicability

This command was introduced before OcNOS-SP version 1.0.

Example

```
(config)#nvo vxlan access-if port-vlan xe2 10
(config-nvo-acc-if)#map qos-profile queue-color-to-cos ac_profile
(config-nvo-acc-if)#no map qos-profile queue-color-to-cos ac_profile
```

nvo vxlan tunnel qos-map-mode cos-dscp

Use this command to map QoS profile for network side to nvo vxlan tunnel. For outgoing/incoming traffic, you need to provide the direction with the keyword `egress`/`ingress`.

Use the `no` form of this command to delete the mapping.

You must give the clear nvo vxlan tunnels command to do the network port setting for QoS profile mapped.

Command Syntax

```
nvo vxlan tunnel qos-map-mode cos-dscp (ingress|egress) NAME
no nvo vxlan tunnel qos-map-mode cos-dscp (ingress|egress)
```

Parameters

`NAME`	QoS profile name for network side
`ingress`	Ingress direction
`egress`	Egress direction

Command Mode

Configure mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
(config)#nvo vxlan tunnel qos-map-mode cos-dscp egress nw_profile
(config)#no nvo vxlan tunnel qos-map-mode cos-dscp egress
(config)#nvo vxlan tunnel qos-map-mode cos-dscp ingress nw_profile
(config)#no nvo vxlan tunnel qos-map-mode cos-dscp ingress
```

qos enable

Use this command to enable QoS globally. By enabling QoS, one-to-one (default) mapping of COS-to-queue is achieved in the hardware. By default, QoS is disabled.

To disable one-to-one mapping of COS-to-queue, use the `disable` form of the command.

Command Syntax

```
qos enable
qos disable
```

Parameters

None

Default

By default, QoS is disabled.

Command Mode

Configure mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
(config)#qos enable
(config)#qos disable

#show running-config  qos
qos enable

(config)#qos disable
```

qos profile cos-to-queue

Use this command to configure cos-to-queue profile. This profile has to be mapped to VXLAN access port on the local VTEP.

Use the no form of this command to delete the qos profile.

Command Syntax

```
qos profile cos-to-queue NAME
```

Parameters

NAME	QoS profile name for cos-to-queue

Command Mode

Configure mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
(config)#qos profile cos-to-queue ac_port_ingress
(config)#no qos profile cos-to-queue ac_port_ingress
```

qos profile dscp-to-queue

Use this command to configure QoS profile for DSCP to Queue mapping. This profile will be mapped to nvo vxlan tunnel of remote VTEP. The created profile will support remarking of the data packets.

Use the no form of this command to delete the QoS profile

Command Syntax

```
qos profile dscp-to-queue NAME
```

Parameters

NAME	QoS profile name for ingress mapping for vxlan tunnel

Command Mode

Configure mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
(config)#qos profile dscp-to-queue nw_profile
(config-ingress-dscp-map)#exit
(config)#no qos profile dscp-to-queue nw_profile
(config)#
```

qos profile queue-color-to-cos

Use this command to configure queue-color-to-cos profile. This profile has to be mapped to VXLAN access port on remote VTEP.

Use the no form of this command to delete the qos profile.

Command Syntax

```
qos profile queue-color-to-cos NAME
```

Parameters

NAME	QoS profile name for queue-color-to-cos

Command Mode

Configure mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
(config)#qos profile queue-color-to-cos ac_profile
(config)#no qos profile queue-color-to-cos ac_profile
```

qos profile queue-color-to-dscp

Use this command to create a QoS profile queue-color-to-dscp. This profile will be mapped to nvo vxlan tunnel of local VTEP. The created profile supports remarking of the data packets.

Note: The profile name of "default" is not supported for VXLAN QoS.

Use the no form of this command to delete the profile.

Command Syntax

```
qos profile queue-color-to-dscp (NAME|default)
no qos profile queue-color-to-dscp (NAME|default)
```

Parameters

NAME	QoS profile name for queue-color-to-dscp

Default

None

Command Mode

Configure mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
(config)#qos profile queue-color-to-dscp nw_profile
(config-egress-dscp-map)#exit
(config)#no qos profile queue-color-to-dscp nw_profile
```

queue cos

Use this command to configure user defined mapping for queue and cos.

Use the no form of this command to remove the mapping.

Command Syntax

```
queue <0-7> cos <0-7>
no queue <0-7>
```

Parameters

queue	Queue number
cos	COS

Default

Default queue and cos value is one-one default mapping if it is not configured.

Command Mode

QoS config mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
(config)#qos profile queue-color-to-cos ac_profile
(config-egress-cos-map)#queue 5 cos 2
(config-egress-cos-map)#no queue 5
```

queue dscp

Use this command to configure user-defined mapping for queue to DSCP. This will be mapped with nvo VXLAN tunnel of local VTEP.

Use the no form of this command to remove the queue-to-DSCP mapping.

Command Syntax

```
queue <0-7> dscp <0-63>
no queue <0-7>
```

Parameters

<0-7>	Queue number
<0-63>	DSCP

Default

Default queue and cos value is one-one default mapping if it is not configured.

Command Mode

Egress-dscp-map mode

Applicability

This command was introduced in OcNOS-SP version 1.0.

Example

```
(config)#qos profile queue-color-to-dscp nw_profile
(config-egress-dscp-map)# queue 1 dscp 63
(config-egress-dscp-map)#no queue 1
```

SECTION 17 Neighbor Discovery

Neighbor Discovery Configuration Guide

Contents

This document contains these chapters:

CHAPTER 1 Neighbor Discovery Configuration

This chapter provides an overview of Neighbor Discovery (ND) configuration.

The Address Resolution Protocol (ARP) translates network layer addresses into link-layer addresses. ARP converts a an IPv4 address to an Ethernet address (MAC address).

In Internet Protocol Version 6 (IPv6) networks, the functionality of ARP is provided by the Neighbor Discovery (ND) protocol. Neighbor Discovery operates at the link layer and is responsible for auto configuration of nodes, discovery of other nodes on the link, determining the link layer addresses of other nodes, duplicate address detection, finding available routers and Domain Name System (DNS) servers, address prefix discovery, and maintaining reachability information about the paths to other active neighbor nodes.

ARP/Neighbor Discovery Operation

Neighbor Discovery module manages the ARP and IPv6 ND entries and provides information to other protocols, the forwarding module for their use, and reports state changes.

Neighbor Entry States

`INCOMPLETE`	Address resolution is in progress and the link-layer address of the neighbor has not yet been determined.
`REACHABLE`	The neighbor is known to have been reachable recently.
`STALE`	The neighbor is no longer known to be reachable (not used by higher level protocol for reachable-time) but still valid and used for forwarding. Until any control packet is sent to the neighbor, no attempt will be made to verify its reachability.
`DELAY`	The neighbor is no longer known to be reachable, and traffic has recently been sent to the neighbor. Rather than probing the neighbor immediately, delay sending probes for a short while in order to give upper-layer protocols chance to provide reachability confirmation.
`PROBE`	The neighbor is no longer known to be reachable, andprobes are being sent to verify reachability.
`FAILED`	Address resolution is failed. No response received from the neighbor.

Below are few timers that control the above state transitions.

1. **reachable-time**
   The amount of time the entry is in REACHABLE state. The default value is 60 seconds.
   Once a neighbor is found, the entry is considered reachable for at least a random value between (A) & (3xA) where

   A = reachable-time /2

   Once entry reachability expires it moves to STALE state. The entry's reachability is extended if it receives positive feedback (ARP reply/NA).

2. **stale-time**
   Determines how often to check for stale neighbor entries. The default value is 1440 seconds.
   Once the stale-timer expires, the entry is marked for garbage collection.

3. **arp-ageing-time**
   The approximate amount of time ARP entry is valid. The default value is 1500 seconds. Ageing time is configured internally as below

   Age-time = reachable-time + stale-time

The garbage collector runs every 60 seconds once, to clean-up the entries which have crossed STALE timeout and FAILED entries. For improved performance benefits, following are the additional criteria for the neighbor entries to be garbage collected i.e. removal of the entry completely.

1. The garbage collector does not run if the total number of entries is less than 2048 that conveys some STALE, and FAILED entries still exist. The entry is refreshed ONLY when higher-level protocols use it.
2. The garbage collector is always run if we have number of entries more than 262144 for Ipv4 & 131072 for Ipv6.

The garbage collection triggers the refresh of neighbor entries which are marked to be garbage collected. A total of 3 retries with a 3 second interval is done to reach the neighbor, before declaring the neighbor as not reachable by the forwarder. During this retry period, neighbor entries are still in use for hardware forwarding. If the neighbor is still not reachable after retries (after 9 seconds), the neighbor entry is removed from hardware forwarding as well.

Configuring ARP for IPV4

The procedures in this section use the topology in Figure 1-131

Figure 1-131: ARP for IPV4

RTR1

`#configure terminal`	Enter the configure mode.
`(config)#interface xe1`	Enter interface mode.
`(config-if)#ip address 2.2.2.2/24`	Configure IP address on the interface.
`(config-if)#exit`	Exit interface mode.
`(config)#ip arp 2.2.2.3 0000.0000.0003`	Configure ARP entry for neighbor.
`(config)#exit`	Exit configure mode.

RTR2

`#configure terminal`	Enter the configure mode.
`(config)#interface xe1`	Enter interface mode.
`(config-if)#ip address 2.2.2.3/24`	Configure IP address on the interface.
`(config-if)#exit`	Exit interface mode.
`(config)#ip arp 2.2.2.2 0000.0000.0004`	Configure ARP entry for neighbor.
`(config)#exit`	Exit configure mode.

Validation

```
#show arp

Flags: D - Static Adjacencies attached to down interface

Total number of entries: 2
Address          Age      MAC Address     Interface  State
10.12.17.1       00:00:29 44e4.d982.274a  eth0       REACHABLE
2.2.2.3             -     0000.0000.0003  xe1        PERMANENT
```

Configuring Neighbor Discovery for IPV6

The procedures in this section use the topology in Figure 1-132.

Figure 1-132: ND for IPv6

RTR1

`#configure terminal`	Enter the configure mode.
`(config)#interface xe1`	Enter interface mode.
`(config-if)#ipv6 address 3ffe:506::1/48`	Configure IPv6 address on the interface.
`(config-if)#exit`	Exit interface mode.
`(config)# ipv6 neighbor 3ffe:506::2 xe1 0000.0000.0004`	Configure neighbor IPv6 address and MAC.
`(config)#exit`	Exit configure mode.

RTR2

`#configure terminal`	Enter the configure mode.
`(config)#interface xe1`	Enter interface mode.
`(config-if)#ipv6 address 3ffe:506::2/48`	Configure IPv6 address on the interface.
`(config-if)#exit`	Exit interface mode.
`(config)# ipv6 neighbor 3ffe:506::1 xe1 0000.0000.0003`	Configure neighbor IPv6 address and MAC.
`(config)#exit`	Exit configure mode.

Validation

```
#show ipv6 neighbors

R - Reachable, I - Incomplete, S - Stale, F - Failed, P - Probe,
D - Delay, PR - Permanent
```

```
Flags: (D) - Static neighbors attached to down interface

IPv6 Neighbor Table for context default
Total number of entries:1
Address        Age       MAC Address     Source  Interface      State
3ffe:506::2      -       0000.0000.0004  static  xe1         PR
```

Neighbor Discovery Command Reference

Contents

This document contains these chapters:

CHAPTER 1 Neighbor Discovery Commands

This chapter provides a description, syntax, and examples of the ND commands. It includes the following commands:

arp-ageing-timeout

Use this command to set the ARP aging timeout.

Note: The bridge aging time affects the ARP entries which are dependent upon the MAC addresses in hardware. If a MAC address ages out, it causes the corresponding ARP entry to refresh.

Use no form of this command to set the aging to its default value.

Command Syntax

```
arp-ageing-timeout <60-28800>
no arp-ageing-timeout
```

Parameter

<60-28800>	ARP aging timeout.

Default value

By default, the ARP aging timeout is 1500.

Command Mode

Interface mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#configure terminal
(config)#interface xe2
(config-if)#arp-ageing-timeout 5000
(config-if)#exit

(config)#interface xe2
(config-if)#no arp-ageing-timeout
```

arp-reachable-time

Use this command to set the ARP reachable time.

Use no form of this command to set the reachable time to its default value.

Command Syntax

```
arp-reachable-time <10-3600>
no arp-reachable-time
```

Parameters

<10-3600>	Specify the ARP reachable time.

Default value

By default, arp-reachable-time is 60

Command Mode

Interface mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#configure terminal
(config)#interface xe2
(config-if)#arp-reachable-time 120
(config-if)#exit

(config)#interface xe2
(config-if)#no arp-reachable-time
```

clear arp

Use this command to clear dynamic ARP entries.

Command Syntax

```
clear arp (| A.B.C.D) (| vrf (all | VRFNAME | default))
clear arp IFNAME (| vrf (all | VRFNAME | default))
```

Parameters

`A.B.C.D`	Specify the IP address of the ARP entry.
`IFNAME`	Specify the name of the interface.
`all`	All VRFs.
`VRFNAME`	VPN routing/forwarding instance name.
`default`	Default VRF.

Command Mode

Exec mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#clear arp
#clear arp xe1
#clear arp 10.10.10.10
#clear arp vrf VRF1
```

clear ipv6 neighbors

Use this command to clear dynamic neighbor entries.

Command Syntax

```
clear ipv6 neighbors (|X:X::X:X) (|vrf (all | VRFNAME | default))
clear ipv6 neighbors IFNAME (|vrf (all | VRFNAME | default))
```

Parameters

`X:X::X:X`	Specify the neighbor's IPv6 address.
`IFNAME`	Specify the name of the interface.
`all`	All VRFs.
`VRFNAME`	VPN routing/forwarding instance name.
`default`	Default VRF.

Command Mode

Exec mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#clear ipv6 neighbors
#clear ipv6 neighbors xe1
#clear ipv6 neighbors 2000::3
#clear ipv6 neighbors vrf VRF1
```

debug ip arp

Use this command to enable debugging for ARP events.

Note: Packet dumps are not available as part of debug logs. Use the `tcpdump` command to view packets.

Use the `no` parameter with this command to disable event debugging.

Command Syntax

```
debug ip arp event
no debug ip arp event
```

Parameters

`event`	ARP event debugging.

Command Mode

Exec mode and configure mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#debug ip arp event
```

debug ipv6 nd

Use this command to enable debugging for neighbor events.

Note: Packet dumps are not available as part of debug logs. Use the `tcpdump` command to view packets.

Use the `no` parameter with this command to disable event debugging.

Command Syntax

```
debug ipv6 nd event
no debug ipv6 nd event
```

Parameters

`event`	ND event debugging.

Command Mode

Exec mode and configure mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#debug ipv6 nd event
```

ip arp

Use this command to create a static ARP entry.

Use the no parameter to remove the static ARP entry.

Command Syntax

```
ip arp A.B.C.D XXXX.XXXX.XXXX (alias|)
no ip arp A.B.C.D
```

Parameters

A.B.C.D	Specify the IP address of the ARP entry.
XXXX.XXXX.XXXX	Specify the MAC (hardware) address of the ARP entry.
alias	Specify the response to ARP requests for the IP address.

Default value

No default value is specified

Command Mode

Configure mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#configure terminal
(config)#ip arp 10.10.10.10 0000.0001.4566
(config)#no ip arp 10.10.10.10
```

ip arp vrf

Use this command to create a static ARP entry for the non-default VRF.

Note: This command is supported only for multiple VRF support.

Command Syntax

```
ip arp vrf NAME A.B.C.D XXXX.XXXX.XXXX (alias|)
```

Parameter

NAME	Specify VRF name to which entry need to be added.
A.B.C.D	Specify the IP address of the ARP entry.
XXXX.XXXX.XXXX	Specify the MAC (hardware) address of the ARP entry.
alias	Specify the response to ARP requests for the IP address.

Default value

No default value is specified

Command Mode

Configure mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#configure terminal
(config)#ip arp vrf VRF1 10.10.10.10 0000.0001.4566
```

ip proxy-arp

Use this command to enable the proxy ARP feature.

Use the no parameter to disable the proxy ARP feature.

Command Syntax

```
ip proxy-arp
no ip proxy-arp
```

Parameter

None

Default value

No default value is specified

Command Mode

Interface mode

Applicability

This command was introduced before OcNOS version 1.3.

Examples

```
#configure terminal
(config)#interface xe1
(config-if)#ip proxy-arp
(config-if)#no ip proxy-arp
```

ipv6 neighbor

Use this command to add a static neighbor entry.

Use the no form of this command to remove a static neighbor entry.

Command Syntax

```
ipv6 neighbor X:X::X:X IFNAME XXXX.XXXX.XXXX
no ipv6 neighbor X:X::X:X IFNAME
```

Parameter

X:X::X:X	Specify the neighbor's IPv6 address.
IFNAME	Specify the name of the interface.
XXXX.XXXX.XXXX	Specify the MAC hardware address.

Default value

No default value is specified

Command Mode

Configure mode

Applicability

This command was introduced before OcNOS version 1.3.

Examples

```
#configure terminal
(config)#ipv6 neighbor 2000::3 xe1 0000.0002.3dc1
(config)#no ipv6 neighbor 2000::3 xe1
```

nd-ageing-timeout

Use this command to set the neighbor ageing timeout value.

Use no form of this command to set the ageing to its default value.

Command Syntax

```
nd-ageing-timeout <60-28800>
no nd-ageing-timeout
```

Parameters

<60-2880>	ND ageing timeout in seconds.
IFNAME	Specify the name of the interface.
XXXX.XXXX.XXXX	Specify the MAC hardware address.

Default value

By default, nd-ageing-timeout is 1500 seconds

Command Mode

Interface mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#configure terminal
(config)#interface xe1
(config-if)#nd-ageing-timeout 3600
(config-if)#no nd-ageing-timeout
```

nd-reachable-time

Use this command to set neighbor reachable time value.

Use no form of this command to set the reachable time to its default value.

Command Syntax

```
nd-reachable-time <10-3600>
no nd-reachable-time
```

Parameter

<10-3600>	ND reachable time in seconds.

Default value

By default, nd-reachable-time is 60 seconds

Command Mode

Interface mode

Applicability

This command was introduced before OcNOS version 1.3.

Examples

```
#configure terminal
(config)#interface xe1
(config-if)#nd-reachable-time 300
(config-if)#no nd-reachable-time
```

no debug all

Use this command to disable all ARP and the neighbor debugging.

Command Syntax

```
no debug all
undebug all
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#no debug all
```

show arp

Use this command to display ARP entry information.

Command Syntax

```
show arp (| (A.B.C.D | detail | static) (| vrf (all | VRFNAME | default)))
show arp IFNAME (| vrf (all | VRFNAME | default))
show arp summary (|IFNAME) (| vrf (all | VRFNAME | default))
```

Parameters

`detail`	Display detailed information.
`static`	Display static ARP entries.
`A.B.C.D`	Specify the IP address of the ARP entry.
`IFNAME`	Specify the name of the interface.
`all`	All VRFs.
VRFNAME	VPN routing/forwarding instance name.
`default`	Default VRF.

Command Mode

Exec mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#show arp

Flags: D - Static Adjacencies attached to down interface

IP ARP Table for context default
Total number of entries: 2
Address          Age      MAC Address     Interface  State
10.12.18.1       00:00:18 44e4.d982.274b  eth0       REACHABLE
10.10.10.20      00:02:33 a8b1.d433.4140  xe1        STALE

#show arp summary vrf default

IP ARP Table - Adjacency Summary

  Resolved   : 2
  Incomplete : 0
  Unknown    : 0
  Total      : 2
```

Table 1-97 explains the show commmand output fields.

Table 1-97: show arp output details

Entry	Description
Address	ARP entry's IP address in the device.
Age	The number of minutes before the ARP entry was refreshed. If this value reaches the ARP aging period, the entry is removed from the table. Static entries do not age out.
MAC Address	Physical address of the host.
Interface	Logical address to connect the device over network.
State	INCOMPLETE – first ARP request sent, send ARP request. REACHABLE – normal expiration reset use counter. STALE – still usable; needs verification reset use counter; change state to delay. DELAY – schedule ARP request; needs verification reset use counter. PROBE – sending ARP request reset use counter. FAILED – no response received send ARP request. NOARP – normal expiration; never verified reset use counter. PERMANENT – never expires; never verified reset use counter. Note: INCOMPLETE/FAILED state entries are only cleared if the total number of ARP entries is more than 2048. It might take up to 60 seconds to clear the entries. This is an optimization to improve ND performance.

Network devices are considered adjacent if they can reach each other with a single hop. The summary command shows the count of the state of devices that are adjacencies.

Table 1-98 explains the show command output fields.

Table 1-98: show arp summary output details

Field	Description
Resolved	Count of working/known adjacencies.
Incomplete	Count of yet to be established adjacencies.
unknown	Count of adjacencies not currently in ARP table.
Total	Total count of all adjacencies.

show debugging ip arp

Use this command to display debugging information for ARP.

Command Syntax

```
show debugging ip arp
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#show debugging ip arp
ND IP Debugging status:
  ND ip arp event debugging is off
  ND ip arp packet debugging is off
```

show debugging ipv6 nd

Use this command to display debugging information for the neighbor.

Command Syntax

```
show debugging ipv6 nd
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#show debugging ipv6 nd
ND IPV6 Debugging status:
  ND ipv6 event debugging is off
  ND ipv6 packet debugging is off
```

show ipv6 neighbors

Use this command to display the neighbor information.

Command Syntax

```
show ipv6 neighbors (| (X:X::X:X | detail | static) (| vrf (all | VRFNAME |
  default)))
show ipv6 neighbors IFNAME (| vrf (all | VRFNAME | default))
show ipv6 neighbors summary (| IFNAME) (| vrf (all | VRFNAME | default))
```

Parameters

`detail`	Show detail information of neighbor.
`static`	Static entry.
`X:X::X:X`	Specify the neighbor's IPv6 address.
`IFNAME`	Specify the name of the interface.
`all`	All VRFs.
`VRFNAME`	VPN routing/forwarding instance name.
`default`	Default VRF.

Command Mode

Exec mode

Applicability

This command was introduced before OcNOS version 1.3.

Example

```
#show ipv6 neighbors

R - Reachable, I - Incomplete, S - Stale, F - Failed, P - Probe,
D - Delay, PR - Permanent

Flags: (D) - Static neighbors attached to down interface

IPv6 Neighbor Table for context default
Total number of entries:2
Address         Age       MAC Address     Source  Interface      State
fe80::210:18ff:fe7f:f758
                00:43:04  0010.187f.f758  icmpv6  eth0             S
2000::5         00:55:25  0000.0001.0242  icmpv6  xe1              S

#show ipv6 neighbors summary

IPv6 Neighbors Table - Adjacency Summary

  Resolved   : 2
  Incomplete : 0
  Unknown    : 0
  Total      : 2
```

Table 1-99 shows the status codes displayed at the start of a route entry.

Table 1-99: status code output details

Status Code	Field	Description
R	Reachable	Normal expiration reset use counter.
I	Incomplete	First ARP request sent, send ARP request.
S	Stale	Still usable; needs verification reset use counter; change state to delay.
F	Failed	ARP requests response not received.
P	Probe	ARP request reset use counter.
D	Delay	Schedule ARP request; needs verification reset use counter.
PR	Permanent	Never expires; never verified reset use counter.

Table 1-100 explains the show command output fields.

Table 1-100: show ipv6 neighbors output details

Field	Description
Address	ARP entry's IP address in the device.
Age	The number of minutes before the ARP entry was refreshed. If this value reaches the ARP aging period, the entry is removed from the table. Static entries do not age out.
MAC Address	Physical address of the host.
Source	ARP request source in the interface.
Interface	Logical address to connect the device over network.
State	ARP request state that is being handled by the IPv6 neighbor session.

Table 1-101 explains the show command output fields.

Table 1-101: show arp summary output details

Field	Description
Resolved	Count of working/known adjacencies.
Incomplete	Count of yet to be established adjacencies.
unknown	Count of adjacencies not currently in ARP table.
Total	Total count of all adjacencies.

SECTION 18 Optical Line Termination

Optical Line Termination Configuration Guide

Contents

This document contains these chapters:

CHAPTER 1 OLT Configuration

Overview

The OcNOS optical line termination or terminal (OLT) device serves as an endpoint of a passive optical network (PON) of the service provider. OcNOS OLT supports XGS-PON which provides 10Gbps symmetric data transmission capability over the fiber network. The OLT allows the service provider to configure the optical network unit (ONU) and send specific traffic required for the service(s) to the subscribers.

Note: TIBIT OLT VM can be accessed by using switch management IP address with port number 2023 for telnet and 2022 for ssh connection.

OLT Configuration

User can create multiple OLT instances and enable the OLT.

```
OcNOS#conf t
Enter configuration commands, one per line.  End with CNTL/Z.
OcNOS(config)#pon-configuration
OcNOS(config-pon)#olt-id 0
OcNOS(config-pon-olt)# serial-number e8:b4:70:70:01:92
```

Note: The serial number of the TIBIT micro-plug can be found using "show pon olt mapping" CLI Serial Number configuration is required only for TIBIT OLT.

Use the OLT configuration to create multiple OLT instances and enable the OLT with 2 ONU provisioning modes as follows:

- Manual provisioning mode or pre-provisioning ONU mode
- Automatic provisioning mode

To enter into OLT configuration mode, execute the following commands:

Note: Currently one OLT (`OLT-ID 0`) instance is supported for ASXvOLT16 and 64 instances are supported for TIBIT OLT.

Manual Provisioning Mode

Use the CLI to configure the ONU provisioning mode as manual to the discovered and connected ONUs to the OLT system manually.

To set the OLT configuration in manual provisioning mode, execute the following commands.

`#configure terminal`	Enter configure mode
`(config)#pon-configuration`	Enter PON configure mode
`(config-pon)# olt-id 0`	Input OLT instance Identifier
`(config-pon-olt)# onu-provisioning-type manual administrative-state up`	Configure manual ONU provisioning mode and enable OLT admin state
`(config-pon-olt)#exit`	Exit configure mode

Validation

This section shows the command(s) and output(s) to validate the configuration.

Execute the `show` command to verify the output.

```
#show pon olt 0

  admin-status:   UP
  oper-status:    UP
  onu-mode:       MANUAL_PROVISION
  dhcp-mode:      ON
  pon-ports:
    (Reason Code: AD - Admin Down
                  DV - DDM Violation
                  PD - Protocol/Port Down)

    PON-PORT-NAME  ADMIN-STATUS  OPER-STATUS  REASON  SPEED
    ------------------------------------------------------
    pon0/0/1       DOWN          DOWN         -       XG-S
    pon0/0/2       DOWN          DOWN         AD      XG-S
    pon0/0/3       DOWN          DOWN         AD      XG-S
    pon0/0/4       DOWN          DOWN         AD      XG-S
    pon0/0/5       DOWN          DOWN         AD      XG-S
    pon0/0/6       DOWN          DOWN         AD      XG-S
    pon0/0/7       DOWN          DOWN         AD      XG-S
    pon0/0/8       DOWN          DOWN         AD      XG-S
    pon0/0/9       DOWN          DOWN         AD      XG-S
    pon0/0/10      DOWN          DOWN         AD      XG-S
    pon0/0/11      DOWN          DOWN         AD      XG-S
    pon0/0/12      DOWN          DOWN         AD      XG-S
    pon0/0/13      DOWN          DOWN         AD      XG-S
    pon0/0/14      DOWN          DOWN         AD      XG-S
    pon0/0/15      DOWN          DOWN         AD      XG-S
    pon0/0/16      DOWN          DOWN         AD      XG-S
  nni-ports:
    (Reason Code: AD - Admin Down
                  DV - DDM Violation
                  PD - Protocol/Port Down)

    NNI-PORT-NAME  ADMIN-STATUS  OPER-STATUS  REASON  SPEED  FEC
    ------------------------------------------------------------
    nni0/0/1       UP            DOWN         PD      100G   OFF
    nni0/0/2       UP            DOWN         PD      100G   OFF
    nni0/0/3       UP            DOWN         PD      100G   OFF
    nni0/0/4       UP            UP           -       100G   OFF
#
```

Automatic Provisioning Mode

Use the CLI to configure the ONU provisioning mode as automatic to the discovered and connected ONUs to the OLT system automatically. The OLT automatically discovers the ONU(s) and program the default profiles.

To set the OLT configuration in automatic provisioning mode, execute the following commands.

`#configure terminal`	Enter configure mode
`(config)#pon-configuration`	Enter PON configure mode
`(config-pon)# olt-id 0`	Input OLT instance Identifier
`(config-pon-olt)# onu-provisioning-type automatic administrative-state up`	Configure automatic ONU provisioning mode and enable OLT admin state
`(config-pon-olt)#exit`	Exit configure mode

Validation

This section shows the command(s) and output(s) to validate the configuration.

Execute the `show` command to verify the output.

```
#show pon olt 0

  admin-status:   UP
  oper-status:    UP
  onu-mode:       AUTOMATIC_PROVISION
  dhcp-mode:      ON
  pon-ports:
    (Reason Code: AD - Admin Down
                  DV - DDM Violation
                  PD - Protocol/Port Down)

    PON-PORT-NAME  ADMIN-STATUS  OPER-STATUS  REASON  SPEED
    ------------------------------------------------------
    pon0/0/1       DOWN          DOWN         -       XG-S
    pon0/0/2       DOWN          DOWN         AD      XG-S
    pon0/0/3       DOWN          DOWN         AD      XG-S
    pon0/0/4       DOWN          DOWN         AD      XG-S

                  PD - Protocol/Port Down)

    NNI-PORT-NAME  ADMIN-STATUS  OPER-STATUS  REASON  SPEED  FEC
    ------------------------------------------------------------
    nni0/0/1       UP            DOWN         PD      100G   OFF
    nni0/0/2       UP            DOWN         PD      100G   OFF
    nni0/0/3       UP            DOWN         PD      100G   OFF
    nni0/0/4       UP            UP           -       100G   OFF
#
```

CHAPTER 2 PON Interface Configuration

Overview

The optical line termination (OLT) configuration includes the following two interfaces:

- PON — Use this interface to connect to ONUs.
- NNI — Use this interface to connect to core network.

The OLT PON interface connects the user and the ONUs. This PON interface is not visible until the OLT configuration is completed.

Note: The PON interface is down by default for ASXvOLT16 and it will be up by default for TIBIT OLT.

To configure the PON interface, execute the following commands:

`#configure terminal`	Enter configure mode.
`(config)# interface pon0/0/1`	Select an interface to configure and IFNAME
`(config-if)#no shut`	Set admin state of interface
`(config-if)#exit`	Exit configuration mode

Validation

This section shows the command(s) and output(s) to validate the configuration.

Execute the `show` command to verify the output.

```
#show pon olt 0 pon-port pon0/0/1

  admin-state:   UP
  oper-status:   UP
  speed:         XG-S

#show pon olt 0 pon-port brief

    (Reason Code: AD - Admin Down
                  DV - DDM Violation
                  PD - Protocol/Port Down)

    PON-PORT-NAME  ADMIN-STATUS  OPER-STATUS  REASON  SPEED
    ------------------------------------------------------
    pon0/0/1       UP            UP           -       XG-S
    pon0/0/2       DOWN          DOWN         AD      XG-S
    pon0/0/3       DOWN          DOWN         AD      XG-S
    pon0/0/4       DOWN          DOWN         AD      XG-S
    pon0/0/5       DOWN          DOWN         AD      XG-S
    pon0/0/6       DOWN          DOWN         AD      XG-S
    pon0/0/7       DOWN          DOWN         AD      XG-S
    pon0/0/8       DOWN          DOWN         AD      XG-S
    pon0/0/9       DOWN          DOWN         AD      XG-S
```

```
    pon0/0/10      DOWN          DOWN          AD      XG-S
    pon0/0/11      DOWN          DOWN          AD      XG-S
    pon0/0/12      DOWN          DOWN          AD      XG-S
    pon0/0/13      DOWN          DOWN          AD      XG-S
    pon0/0/14      DOWN          DOWN          AD      XG-S
    pon0/0/15      DOWN          DOWN          AD      XG-S
    pon0/0/16      DOWN          DOWN          AD      XG-S
#
```

NNI Interface Configuration

OLT NNI interface connects to the core network. The NNI port supports 40G and 100G speed interfaces. The user can configure the speed of the NNI interface. The Forward Error Correction (FEC) is disabled for 100G interface by default while it is not applicable for 40G interface.

Note: The NNI interface by default enables the admin state to up and supports100G speed for ASXvOLT16 only. Speed change command is not applicable to NNI interface on TIBIT OLT and default speed is 10G.

To configure the speed of the NNI interface, execute the following commands:

`#configure terminal`	Enter configure mode
`(config)# interface nni0/0/1`	Select an interface to configure and IFNAME
`(config-if)# speed 40g`	Set interface port speed to 40G
`(config-if)#exit`	Exit configuration mode

Validation

This section shows the command(s) and output(s) to validate the configuration.

Execute the `show` command to verify the output on ASXvOLT16.

```
#show pon olt 0 nni-port nni0/0/1

  admin-state:   UP
  oper-status:   UP
  speed:         40G
  fec:           OFF
#
```

Execute the `show` command to verify the output on TIBIT OLT.

```
#show pon olt 0 nni-port nni0/0/1

 admin-state:UP
 oper-status:UP
 speed:10G
#
```

FEC Configuration

OLT supports Forward Error Correction (FEC) with 100G speed for the NNI interface.

Note: FEC config for NNI interface is not supported on TIBIT OLT.

`#configure terminal`	Enter configure mode
`(config)# interface nni0/0/4`	Select an interface to configure and IFNAME
`(config-if)# FEC on`	Enable FEC
`(config-if)#exit`	Exit configuration mode

Validation

This section shows the command(s) and output(s) to validate the configuration.

Execute the `show` commands to verify the output.

```
#show pon olt 0 nni-port brief

    (Reason Code: AD - Admin Down
                  DV - DDM Violation
                  PD - Protocol/Port Down)

    NNI-PORT-NAME  ADMIN-STATUS  OPER-STATUS  REASON  SPEED  FEC
    ------------------------------------------------------------
    nni0/0/1       UP            DOWN         PD      100G   OFF
    nni0/0/2       UP            DOWN         PD      100G   OFF
    nni0/0/3       UP            DOWN         PD      100G   OFF
    nni0/0/4       UP            UP           -       100G   ON

#show pon olt 0 nni-port nni0/0/4

  admin-state:   UP
  oper-status:   UP
  speed:         100G
  fec:           ON
#
```

CHAPTER 3 ONU-Profile Configuration

Overview

Use ONU Profile to create a `onu-profile` and associate with the ONU. The ONU-profile configuration allows the OLT user to configure one GEM-port to one T-Cont and assign this to logical UNI-Port. The ONU-profile associates with the actual ONU.

OLT allows to configure the profile-name of the `onu-profile` with maximum of 32-characters.

To configure a ONU profile, execute the following commands:

`#configure terminal`	Enter configure mode
`(config)#pon-configuration`	Configure PON parameters
`(config-pon)# onu-profile profile-name Sample1`	Input ONU profile name

UNI Port-ID and GEM port Configuration

OLT allows user to create logical UNI Port-ID and GEM port to send upstream and downstream traffic of a specific p-bit.

To configure a UNI and GEM port, execute the following commands:

`#configure terminal`	Enter configure mode
`(config)#pon-configuration`	Enter PON configure mode
`(config-pon)# onu-profile profile-name onu_prof1`	Configure ONU profile-name
`(config-pon-op)# uni port-id 0`	Input UNI logical port id and UNI port ID value
`(config-pon-op-uni)#gem-port-name GEM0 p-bits 0 upstream-priority-queue 0 downstream-priority-queue 0`	Input Gem port identifier, GEM port name, p-bits range, upstream priority queue, upstream priority queue
`(config-pon-op-uni)#exit`	Exit configuration mode

T-CONT Configuration

The T-Cont configuration allows user to configure T-Cont with unique name and associate the GEM-Port to the T-Cont.

To configure the T-CONT interface, execute the following commands:

`#configure terminal`	Enter configure mode
`(config)#pon-configuration`	Configure PON parameters
`(config-pon)# onu-profile profile-name Sample1`	Input ONU profile name
`(config-pon-op)# t-cont TC01`	Input T-Cont name
`(config-pon-op-tcont)#gem-port-name GEM0`	Input Gem port identifier, gem-port name
`(config-pon-op-tcont)#exit`	Exit configuration mode

Validation

This section shows the command(s) and output(s) to validate the configuration.

Execute the `show` command to verify the output.

```
#show pon onu-profile brief

  default_onu_profile
  Sample1

#show pon onu-profile Sample1

  onu-tconts:
    T-CONT-NAME
    -----------
    TC01
  gem-ports:
    GEM-PORT-NAME        TCONT-NAME           UNI-PORT-ID   P-BITS   US-PQ   DS-PQ
    ------------------------------------------------------------------------------
    GEM0                 TC01                 0             0        0       0
  uni-logic-ports:
    UNI-LOGIC-PORT-ID
    -----------------
    0
#
```

Note: Associate only one GEM-Port to one T-Cont.

Logical UNI Port-ID is linked to Physical UNI port ID.

Note: Maximum 8 T-Conts are supported per ONU.

CHAPTER 4 Translation-Profile Configuration

Overview

Use Translation Profile to filter the ingress traffic based on specific vlan-type traffic type and allow only specific traffic for services.

Untagged Traffic Classification Configuration

To configure a translation profile with untagged classification, execute the following commands.

`#configure terminal`	Enter configure mode
`(config)#pon-configuration`	Configure PON parameters
`(config-pon)# translation-profile profile-name Untag_Sample`	Create a translation profile name
`((config-pon-tp)#classification`	Enter match rule for translation profile name.
`(config-pon-tp-classification)#vlan-type untagged`	Configure untag vlan-type match rule
`(config-pon-tp-tcont)#exit`	Exit configuration mode
`(config-pon-tp)#treatment`	Apply action on configured match rule
`(config-pon-tp-treatment)#p-bits 0 operation none`	Configure the outgoing vlan parameters, output p-bits, and operation to perform
`(config-pon-tp-treatment)#exit`	Exit configuration mode

UNI Port-ID and GEM port Configuration

The OLT allows user to create logical UNI port identifier and GEM port identifier to send upstream and downstream traffic of a specific p-bit.

To configure a logical link between UNI and GEM port, execute the following commands.

`#configure terminal`	Enter configure mode
`(config)#pon-configuration`	Enter PON configure mode
`(config-pon)# onu-profile profile-name onu_prof1`	Configure ONU profile-name
`(config-pon-op)# uni port-id 0`	Input UNI logical port id and UNI port ID value
`(config-pon-op-uni)#gem-port-name GEM0 p-bits 0 upstream-priority-queue 0 downstream-priority-queue 0`	Inpute GEM port identifier, GEM port name, p-bits range value, upstream priority queue value.
`(config-pon-op-uni)#exit`	Exit configuration mode

Validation

This section shows the command(s) and output(s) to validate the configuration.

Execute the `show` command to verify the output.

```
#show pon translation-profile Untag_Sample

  ------------------------------------------------------------------------------
                            |         CLASSIFICATION          |     TREATMENT
  TRANS-PROFILE-NAME        | VLAN-TYPE      VLAN-ID  P-BITS | OPERATION    P-BITS
  ------------------------------------------------------------------------------
  Untag_Sample                UNTAGGED       0        0        NONE         0
#
```

Tagged Traffic Classification Configuration

To configure a translation profile with tagged classification, execute the following commands.

`#configure terminal`	Enter configure mode
`(config)#pon-configuration`	Configure PON parameters
`(config-pon)# translation-profile profile-name Tag_Sample`	Enter translation profile name
`((config-pon-tp)#classification`	Enter match rule for translation profile name
`(config-pon-tp-classification)# vlan-type tagged vlan-id 10 p-bits 0`	Configure tagged vlan-type match rule. Input vlan type tagged, vlan identifier, p-bits range value
`(config-pon-op-tcont)#exit`	Exit configuration mode
`(config-pon-tp)#treatment`	Apply action on configured match rule
`(config-pon-tp-treatment)#p-bits 0 operation remove-vlan`	Configure the outgoing vlan parameters, output p-bits, and operation to perform
`(config-pon-tp-treatment)#exit`	Exit configuration mode

Validation

This section shows the command(s) and output(s) to validate the configuration.

Execute the `show` command to verify the output.

```
#show pon translation-profile Tag_Sample

  ------------------------------------------------------------------------------
                            |         CLASSIFICATION          |     TREATMENT
  TRANS-PROFILE-NAME        | VLAN-TYPE      VLAN-ID  P-BITS | OPERATION    P-BITS
  ------------------------------------------------------------------------------
  Tag_Sample                  TAGGED         10       0        REMOVE_VLAN  0
#
```

Priority-Tagged Traffic Classification Configuration

To configure a translation profile with priority tagged classification, execute the following commands.

`#configure terminal`	Enter configure mode
`(config)#pon-configuration`	Configure PON parameters
`(config-pon)# translation-profile profile-name PriorityTag _Sample`	Enter translation profile name
`((config-pon-tp)#classification`	Enter match rule for translation profile name
`(config-pon-tp-classification)# vlan-type prioritytagged p-bits 0`	Configure priority tagged vlan-type match rule. Input vlan type priority tagged, p-bits range value
`(config-pon-tp-tcont)#exit`	Exit configuration mode
`(config-pon-tp)#treatment`	Apply action on the configured match rule
`(config-pon-tp-treatment)#p-bits 0 operation remove-vlan`	Configure the outgoing vlan parameters, output p-bits, and operation to perform
`(config-pon-tp-treatment)#exit`	Exit configuration mode

Validation

This section shows the command(s) and output(s) to validate the configuration.

Execute the `show` command to verify the output.

```
#show pon translation-profile PriorityTag_Sample

  ------------------------------------------------------------------------------
                            |         CLASSIFICATION         |     TREATMENT
  TRANS-PROFILE-NAME        | VLAN-TYPE      VLAN-ID  P-BITS | OPERATION    P-BITS
  ------------------------------------------------------------------------------
  PriorityTag_Sample          PRIORITYTAGGED 0        0        REMOVE_VLAN  0
#
```

Note: Remove-Vlan operation is not supported for `Vlan-Type Untagged.`

None operation is not supported for `Vlan-Type Tagged` and `Priority Tagged`.

CHAPTER 5 QoS-Profile Configuration

Overview

Use Quality of Service (Qos) profile to configure a generic mechanism to describe the QoS parameters such as Committed, Peak Information Rate and Burst Size for upstream and downstream data traffic.The OLT allows user to configure the CIR and PIR parameters in kbps, mbps and gbps units.

To configure QoS parameters, execute the following commands.

`#configure terminal`	Enter configure mode
`(config)#pon-configuration`	Configure PON parameters
`(config-pon)# qos-profile profile-name QoS_Sample`	Configure qos-profile name
`(config-pon-qp)# upstream`	Enter QOS upstream config mode
`(config-pon-qp-upstream)# cir 100 mbps pir 101 mbps`	Input Committed Information Rate units value, Peak Information Rate units value
`(config-pon-qp-upstream)#exit`	Exit configuration mode
`(config-pon-qp)#downstream`	Enter QOS downstream config mode
`(config-pon-qp- downstream)# cir 150 mbps pir 151 mbps pbs 1 mbytes`	Specify Committed Information Rate units value, Peak Information Rate units value
`(config-pon-qp- downstream)#exit`	Exit configuration mode

Note: Ensure the CIR value is less than PIR value by at least 128 kbps.

The maximum CIR varies based on the number of ONUs connected.

Validation

This section shows the command(s) and output(s) to validate the configuration.

Execute the `show` commands to verify the output.

```
#show pon qos-profile brief

  default_qos_profile
  QoS_Sample

#show pon qos-profile QoS_Sample

  *CIR - Committed Information Rate
  *PIR - Peak Information Rate
  *PBS - Peak Burst Size

  dn-stream-rate-policer:
    CIR      CIR_UNITS      PIR      PIR_UNITS      PBS      PBS_UNITS

#
```

CHAPTER 6 ONU Configuration

Overview

Configure the user end ONU equipment using the ONT management control interface (OMCI) of the OLT. The ONU is configured manually in manual mode where as it is configured automatically in the automatic mode after the ONC is discovered. Refer to Chapter 2, *PON Interface Configuration*.

To configure ONU, execute the following commands.

`#configure terminal`	Enter configure mode
`(config)#pon-configuration`	Configure PON parameters
`(config-pon)# onu-id 0`	Input ONU identifier
`(config-pon-onu)# olt olt-id 0 pon-port pon0/0/1 serial-number 414C5048E3BB87DE profile-name Sample1`	Input optical line termination Identifier value, PON port interface for ONU, PON port serial number for ONU, corresponding ONU profile name

Validation

This section shows the command(s) and output(s) to validate the configuration.

Execute the `show` command to verify the output.

```
#show pon onu brief

  ONU-ID     OLT-ID   ADMIN-STATE OPER-STATUS     PON-PORT     SERIAL#
  ------------------------------------------------------------------------
  0          0        UP          UP              pon0/0/1
414C5048E3BB87DE(ALPHE3BB87DE)
#show pon onu 0
  pon-port-name:     pon0/0/1

```

```
    ------------------------------------------------
    0             LOCKED        ENABLED       Unknown
#
```

ONU UNI PORT Configuration

The ONU UNI Port is a physical port in the ONU equipment.The OLT user has the control over the administrative status of the UNI port.

To configure UNI port, execute the following commands.

`#configure terminal`	Enter configure mode
`(config)#pon-configuration`	Configure PON parameters
`(config-pon)# onu-id 0`	Input ONU identifier
`(config-pon-onu)# uni-port-id 0`	Input UNI port identifier
`(config-pon-onu-uni)#administrative-state unlock`	Unlock the physical port usage
`(config-pon-onu-uni)#exit`	Exit configuration mode

Validation

This section shows the command(s) and output(s) to validate the configuration.

Execute the `show` command to verify the output.

```
#show pon onu 0

  pon-port-name:     pon0/0/1
  olt-id:            0
  serial#:           414C5048E3BB87DE(ALPHE3BB87DE)
  onu-profile-name:  Sample1
  admin-state:       UP
  oper-status:       UP

#
```

CHAPTER 7 Flow Configuration

Overview

Use Flow configuration to provision a specific VLAN type required for the subscriber service(s). The OLT user can configure one or more flow per UNI port with different S+C VLAN combinations.

Note: The flow parameters for active flows cannot be updated on the fly. To update the flow, delete it and create it afresh with new values.

Topology

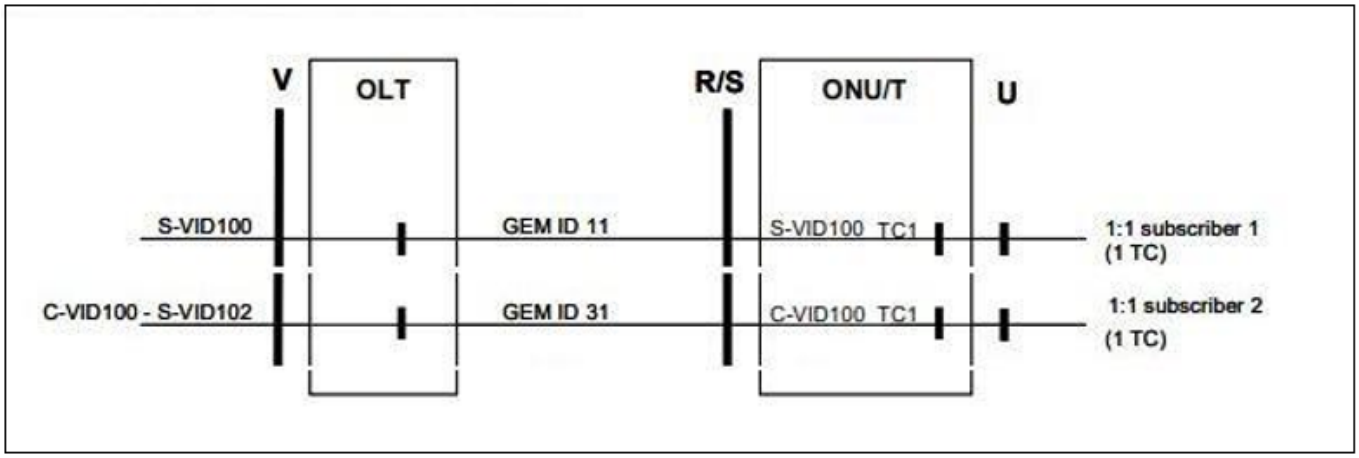

Figure 7-133: Subscriber Service Flow Configuration

S-Vlan Flow Configuration

Use S-Vlan flow configuration to allow the Untag or Tagged or Priority-Tagged traffic from user to S-Tag traffic.

To configure S-Vlan flow, execute the following commands.

`#configure terminal`	Enter configure mode
`(config)#pon-configuration`	Configure PON parameters
`(config-pon)# flow-id 0`	Input Flow identifier
`(config-pon-flow)#uni`	Enter UNI config flow mode
`(config-pon-flow-uni)#onu-id 0 uni-port-id 0 vlan-tag 100 translation-profile-name Untag_Sample`	Input ONU id, UNI port id, vlan-tag, translation profile name for flow
`(config-pon-flow-uni)#exit`	Exit configuration mode
`(config-pon-flow)#nni`	Enter NNI config flow mode

(config-pon-flow-nni)#olt-id 0 nni-port-name nni0/0/1	Input OLT id, NNI port name for flow
(config-pon-flow-nni)#exit	Exit configuration mode
(config-pon-flow)#qos	Enter QoS config flow mode
(config-pon-flow-qos)#qos-profile-name QoS_Sample	Input QoS Profile name
(config-pon-flow-qos)#exit	Exit configuration mode

Validation

This section shows the command(s) and output(s) to validate the configuration.

Execute the show command to verify the output.

```
#show pon flow brief

    FLOW-ID       FLOW-OPER-STATUS
    ------------------------------
    0             UP

#show pon flow 0

  flow-oper-status:     UP
  pon-port:             pon0/0/1
  uni-end:

```

S+C-Vlan Flow Configuration

Use S+C-Vlan flow configuration to allow the Untag or Tagged or Priority-Tagged traffic from user to S+C-Tag traffic.

To configure S+C Vlan, execute the following commands.

`#configure terminal`	Enter configure mode
`(config)#pon-configuration`	Configure PON parameters
`(config-pon)# flow-id 1`	Input Flow identifier
`(config-pon-flow)#uni`	Enter UNI config flow mode
`(config-pon-flow-uni)#onu-id 0 uni-port-id 0 vlan-tag 100 translation-profile-name Tag_Sample`	Input ONU id, UNI Port id, vlan-tag, translation profile name for flow
`(config-pon-flow-uni)#exit`	Exit configuration mode
`(config-pon-flow)#nni`	Enter NNI config for flow mode
`(config-pon-flow-nni)#olt-id 0 nni-port-name nni0/0/1 vlan-tag 102`	Input OLT id, NNI port name, vlan-tag for flow
`(config-pon-flow-nni)#exit`	Exit configuration mode
`(config-pon-flow)#qos`	Enter QoS config for flow mode
`(config-pon-flow-qos)#qos-profile-name QoS_Sample`	Input QoS Profile name
`(config-pon-flow-qos)#exit`	Exit configuration mode

Validation

This section shows the command(s) and output(s) to validate the configuration.

Execute the `show` command to verify the output.

```
#show pon flow brief

    FLOW-ID       FLOW-OPER-STATUS
    ------------------------------
    0             UP
    1             UP

#show pon flow 1

    id     priority direction  action      protocol remote-port   remote-ip
    ------------------------------------------------------------------------
```

CHAPTER 8 ACL Configuration

Overview

An access control list (ACL) consists a list of access control entries (ACE) which specifies the access privilege to allow or deny the flow service. The data packet arrives at the device is compared against each ACE, in the order defined in the ACL, until a match is found. When the device exhaust the ACE list and found no match, then it allows the data packet. If a match is found, then stops checking the access control list and deny the data packet.

Use ACL Configuration to specify ACL rule for each flow services. The ACL configuration can be used in Flow service only.

To configure ACL list, execute the following commands.

`#configure terminal`	Enter configure mode
`(config)#pon-configuration`	Configure PON parameters
`(config-pon)# flow-id 0`	Input flow identifier
`(config-pon-flow)#acl`	Enter ACL config flow mode
`(config-pon-flow-acl)#pon-acl-id 10 priority 10 action drop direction upstream remote-ip 10.10.10.10 protocol any`	Input ACL rule identifier, priority, action for matching ACL rule, direction for ACL rule criteria, upstream destination IP for ACL rule criteria, Layer 4 protocol for ACL rule criteria
`(config-pon-flow-acl)#pon-acl-id 20 priority 20 action allow direction downstream remote-ip 20.20.20.20 protocol any`	Input ACL rule identifier, priority, action for matching ACL rule, direction for ACL rule criteria, downstream source IP for ACL rule criteria, Layer 4 protocol for ACL rule criteria
`(config-pon-flow-acl)#exit`	Exit configuration mode

Note: Remote-port parameter is optional which results in performing specific ACL rule action if packet matches with protocol-port.

Note: ACL configuration is not supported for TIBIT OLT.

Validation

This section shows the command(s) and output(s) to validate the configuration.

Execute the `show` command to verify the output.

```
#show pon acl all

==================== Flow ID: 0 ====================
    id     priority direction  action      protocol remote-port   remote-ip
    ------------------------------------------------------------------------

```

CHAPTER 9 DHCP Configuration

Overview

Use the DHCP configuration to enable or disable the DHCP service. The OLT supports Layer2 DHCP relay with Option-82 (Agent Circuit ID) to forward the DHCP packets from the subscribers to the DHCP server.

DHCP Enable/Disable

Execute the following commands to enable or disable the DHCP service.

`#configure terminal`	Enter configure mode
`(config)#pon-configuration`	Configure PON parameters
`(config-pon)# olt-id 0`	Input OLT Identifier
`(config-pon-olt)# dhcp on`	Enable or disable DHCP relay option-82 for OLT. Use on/off values
`(config-pon-olt)#exit`	Exit configuration mode

Validation

This section shows the command(s) and output(s) to validate the configuration.

Execute the `show` command to verify the output.

```
#show pon olt 0

  admin-status:   UP
  oper-status:    DOWN
  onu-mode:       MANUAL_PROVISION
  dhcp-mode:      ON
  pon-ports:
  nni-ports:
    (Reason Code: AD - Admin Down
                  DV - DDM Violation
                  PD - Protocol/Port Down)
```

CHAPTER 10 OLT Statistics

Overview

The OLT configuration supports to view the statistics of NNI, PON and UNI interfaces.The PON or NNI statistics displays TX, RX bytes, TX, RX Packets, TX, RX Drop packets count for Error packets.

Note: Tx drop packet count is not supported for PON and NNI port in TIBIT OLT.

NNI Statistics

The NNI Port statistics displays TX-Bytes, RX-Bytes, TX- PKTS, RX- PKTS, TX-DROP-PKTS, RX-DROP-PKTS counters.

Execute the following commands to display statistics.

```
#show pon statistics nni-port brief

  NNI port: nni0/0/1
    RX-PKTS     RX-BYTES      TX-PKTS     TX-BYTES      RX-DROP-PKT TX-DROP-PKT
    ------------------------------------------------------------------------
    0           0             0           0             0           0
  NNI port: nni0/0/2
    RX-PKTS     RX-BYTES      TX-PKTS     TX-BYTES      RX-DROP-PKT TX-DROP-PKT
    ------------------------------------------------------------------------
    0           0             0           0             0           0
  NNI port: nni0/0/3
    RX-PKTS     RX-BYTES      TX-PKTS     TX-BYTES      RX-DROP-PKT TX-DROP-PKT
    ------------------------------------------------------------------------
    0           0             0           0             0           0
  NNI port: nni0/0/4
    RX-PKTS     RX-BYTES      TX-PKTS     TX-BYTES      RX-DROP-PKT TX-DROP-PKT
    ------------------------------------------------------------------------
    0           0             0           0             0           0

#show pon statistics nni-port nni0/0/1
  NNI port: nni0/0/1
    RX-PKTS     RX-BYTES      TX-PKTS     TX-BYTES      RX-DROP-PKT TX-DROP-PKT
    ------------------------------------------------------------------------
    0           0             0           0             0           0
#
```

PON Statistics

The PON Port statistics displays TX-Bytes, RX-Bytes, TX- PKTS, RX- PKTS, TX-DROP-PKTS, RX-DROP-PKTS counters.

Execute the following commands to display statistics.

```
#show pon statistics pon-port brief
```

```
PON port: pon0/0/1
  RX-PKTS     RX-BYTES      TX-PKTS     TX-BYTES      RX-DROP-PKT TX-DROP-PKT
  ------------------------------------------------------------------------
  361         17328         355         17040         0           0
PON port: pon0/0/2

CHAPTER 11 Logging and Debugging

Overview

Use the OLT logging option to set the console log level and enable PON log debugging. It allows the user to collect and capture the pon, omci event logs.

Execute the following commands to set logging level and enable PON log debugging.

`#configure terminal`	Enter configure mode
`(config)#logging level pon 7`	Set logging level for PON messages
`(config)#exit`	Exit config mode
`#debug pon`	Enable PON debugging

Disable Logging and Debugging

Execute the following commands to disable PON log debugging.

```
#no debug pon
#show debugging pon

  PON State Machine debugging is OFF
  PON Task debugging is OFF
  PON OMCI debugging is ON
  PON NSM client debugging is OFF
```

CHAPTER 12 VLAN N:1 Configuration

Overview

For N:1 VLAN model, the ONT always adds the S-VLAN ID or translate an incoming tag to S-VLAN ID for upstream traffic. The OLT will pass-through any upstream traffic with S-VLAN ID on them. In the downstream direction, the OLT will pass-through traffic with S-VLAN ID to ONT by determining GEM Port based on MAC address and priority bits. If the GEM Port cannot be determined, then the frame is flooded using the unidirectional GEM Port associated with the S-VLAN ID. The ONT will remove the tag and forward frames from the GEM Port to appropriate U interface. For N:1 model, traffic is always single-tagged at V interface.

Topology

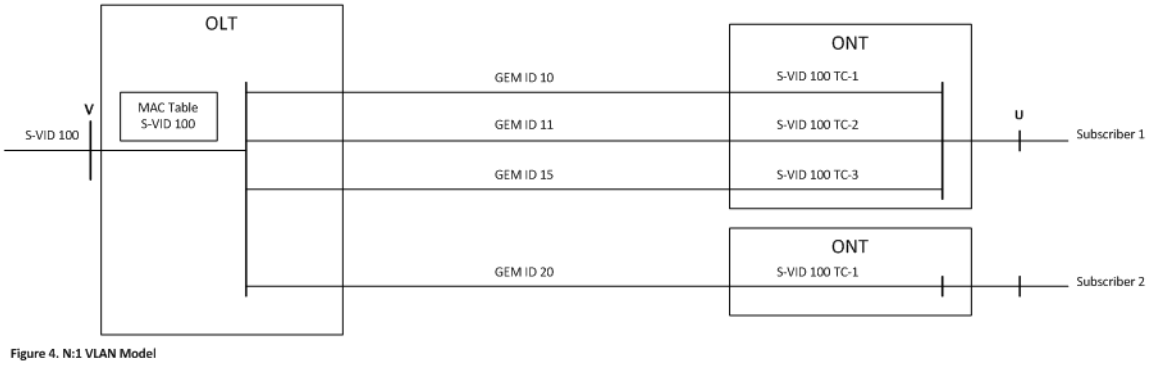

Figure 12-134: Subscriber Service Flow Configuration

VLAN n2one Flow Configuration

Configure ONU to add S-TAG or translate the incoming tag to right S-TAG for upstream traffic. OLT must program ONU such that S-VID should be removed/translated for the downstream traffic.

To configure S-VLAN flow for VLAN n2one, execute the following commands.

`#configure terminal`	Enter configure mode
`(config)#pon-configuration`	Configure PON parameters
`(config-pon)# flow-id 0 mode n2one`	Input Flow identifier for mode n2one
`(config-pon-flow)#uni`	Enter UNI config flow mode
`(config-pon-flow-uni)#onu-id 0 uni-port-id 2 vlan-tag 101 translation-profile-name Untag_Sample ethertype 0x88a8`	Input ONU id, UNI port ID, vlan-tag, translation profile name for flow and ethertype should be 0x88a8 always for tibit
`(config-pon-flow-uni)#exit`	Exit PON flow UNI configuration mode
`(config-pon-flow)#nni`	Enter NNI config flow mode
`(config-pon-flow-nni)#olt-id 0 nni-port-name nni0/0/1 vlan-tag none`	Input OLT ID, NNI port name for flow

`(config-pon-flow-nni)#exit`	Exit configuration mode
`(config-pon-flow)#qos`	Enter QoS config flow mode
`(config-pon-flow-qos)#qos-profile-name QoS_Sample`	Input QoS Profile name
`(config-pon-flow-qos)#exit`	Exit configuration mode

Note: Ethertype field can be 0x8100 or 0x88a8 for UNI in case of AsxVolt16 but in tibit it should be always 0x88a8

Validation

This section shows the command(s) and output(s) to validate the configuration.

Execute the `show` command to verify the output.

```
#show pon flow brief

    FLOW-ID       FLOW-OPER-STATUS
    ------------------------------
    0             UP

OcNOS#sh pon flow 0

```

CHAPTER 13 TC Layer Encryption Configuration

Overview

TC layer which is equivalent to Data Link layer of OSI model. It specifies GPON frame format, the media access control protocol, OAM processes and information encryption method. This TC layer encryption will do the encryption between OLT and ONU.

TC Layer Encryption Enable/Disable

Execute the following commands to enable or disable the TC layer encryption.

`#configure terminal`	Enter configure mode
`(config)#pon-configuration`	Configure PON parameters
`OcNOS(config-pon)# olt-id 0`	Input OLT Identifier
`OcNOS(config-pon-olt)#  serial-number 70:b3:d5:52:35:46`	Configure OLT serial number
`OcNOS(config-pon-olt)#  encryption on`	Enable the Encryption
`(config-pon-olt)# encryption off`	Disable the Encryption
`OcNOS(config-pon-olt)#  key-time 100`	Set the keytime on OLT
`(config-pon-olt)#exit`	Exit PON ONU configuration mode

Validation

This section shows the command(s) and output(s) to validate the configuration.

Enable Encryption on Tibit

Change encryption on/off on Tibit platform requires pon port to be disabled. Disable PON port will affect ONU and flows.

Enable encryption before OLT configuration

```
OcNOS(config)#pon
OcNOS(config-pon)# olt-id 0
OcNOS(config-pon-olt)#  serial-number 70:b3:d5:52:35:46
OcNOS(config-pon-olt)#  encryption on
OcNOS(config-pon-olt)#  key-time 100
OcNOS(config-pon-olt)#  onu-provisioning-type automatic administrative-state up
```

Show command encryption stats before/after flow setup

```
OcNOS#show pon statistics pon-port pon0/0/1 onu 0 encryption

PON port = pon0/0/1 ONU_ID = 0
        encrypted_bytes  encrypted_pkts          plain_bytes      plain_pkts
-------------------------------------------------------------------------
```

```
TX                16224             338                    0               0
RX                    0               0                16512             344
Delete OLT and config without encryption

Check encryption stats before/after flow setup
OcNOS#show pon statistics pon-port pon0/0/1 onu 0 encryption

PON port = pon0/0/1 ONU_ID = 0
        encrypted_bytes  encrypted_pkts          plain_bytes      plain_pkts
-------------------------------------------------------------------------------
TX                    0               0                16176             337
RX                    0               0                16464             343
```

Enable Encryption on ASXvOLT-16

Enable encryption on ONU

```
OcNOS(config)#pon
OcNOS(config-pon)# onu-id 0
OcNOS(config-pon-onu)#  encryption on
OcNOS(config-pon-olt)#  key-time 100
```

Note: `show pon statistics` won't supported by ASXvOLT-16

CHAPTER 14 sFlow Configuration

Overview

sFlow is used for monitoring high speed switched networks. It gives complete visibility into the use of networks enabling performance optimization.

sFlow Enable/Disable

Execute the following commands to enable or disable the sFlow.

`#configure terminal`	Enter configure mode
`OcNOS(config)#feature sflow`	To Enable sFlow
`OcNOS(config)# sflow collector <ip-add> port <int> receiver-time-out 0`	To enable sFlow collector
`OcNOS(config)#interface pon0/0/1`	To Enter into PON port interface
`OcNOS(config-if)#sflow poll-interval <time-period>`	To Set the sFlow interval time
`OcNOS(config)#interface nni0/0/1`	To Enter into NNI interface
`OcNOS(config-if)#sflow poll-interval <time-period>`	To set the sFlow interval time
`OcNOS(config)#no feature sflow`	To Disable the sFlow
`OcNOS#show sflow brief`	This command will show the sFlow in brief
`OcNOS#show sflow detail`	This command will show the sFlow in detail
`OcNOS#show sflow interface pon0/0/1`	This will show the sFlow details on selected PON port
`OcNOS#show sflow interface nni0/0/1`	This will show the sFlow details on selected NNI interface
`OcNOS#show sflow statistics interface pon0/0/1`	This will show the sFlow statistics on selected PON onterface

Validation

This section shows the command(s) and output(s) to validate the configuration.

Enabling sFlow

```
OcNOS(config)#feature sflow
```

Adding sFlow collector

```
OcNOS(config)#sflow collector 172.29.1.99 port 6343 receiver-time-out 0 max-datagram-size 200
```

Enabling sFlow counter sampling on interface

```
OcNOS(config)#interface pon0/0/1
OcNOS(config-if)#sflow poll-interval 5
OcNOS(config-if)#exit
```

```
OcNOS(config)#interface nni0/0/1
OcNOS(config-if)#sflow poll-interval 5
```

Disabling the sFlow collector

```
OcNOS(config)#no sflow collector 172.29.1.99 port 6343 receiver-time-out 0 max-
datagram-size 200

#show sflow output
OcNOS#show sflow detail

CHAPTER 15 Jumbo Frame Configuration

Overview

Jumbo frames are network-layer PDUs that have a size much larger than the typical 1500 byte Ethernet MTU size. TIBIT supports jumbo frame MTU of size of 9000 bytes and alpha ONU supports MTU of size 8968 bytes.

To Configure Jumbo Frame Size

Execute the following commands to configure the jumbo frame size on UNI port.

`#configure terminal`	Enter configure mode
`(config)#pon-configuration`	Enter PON configure mode
`(config-pon)# onu-id 0`	Input ONU Identifier
`(config-pon-onu)#uni-port-id 0`	Input UNI port-ID
`OcNOS(config-pon-onu-uni)#mtu 6000`	Input the MTU for the UNI port
`(config-pon-olt)#exit`	Exit PON ONU configuration mode

Validation

This section shows the command(s) and output(s) to validate the configuration.

Execute the `config and show` command to verify the output.

```
OcNOS(config-pon-onu-uni)#mtu 6000

CHAPTER 16 Rogue ONU detection and Isolation

Overview

A method of detecting a rogue ONU is an OLT detects an abnormal upstream traffic form the ONU to OLT. This will impact the other working ONUs which are connected on the OLT. The intention of this feature is to determine and isolate the rogue ONU from the OLT. This will help in smooth upstream transmission for the right ONUs.

Rogue ONU detection configuration

Execute the following commands to enable or disable the rogue ONU detection.

`#configure terminal`	Enter configure mode.
`(config)#pon-configuration`	Configure PON parameters.
`(config-pon)# onu-rogue-detection pon-port IFNAME`	Enabling rogue ONU detection for PON port.
`config-pon)# no onu-rogue-detection pon-port IFNAME`	Disabling rogue ONU detection for PON port.
`config-pon)# clear pon onu rogue onu serial-number <SERIAL_NUMER>`	To clear the rogue ONU data using ONU serial Number.
`(config-pon)# clear pon onu rogue pon-port <PON_PORT>`	To clear the rogue ONU data using pon-port-id.
`(config-pon)# onu isolate serial-number <SERIALNUMBER>  pon-port <IFNAME>)`	To isolate the rogue ONU using serial number or pon port.
`(config-pon)# no onu isolate serial-number <SERIALNUMBER>  pon-port <IFNAME>)`	To restore back the rogue ONU from isolate the rogue ONU using serial number or pon port.
`(OcNOS#show pon onu-rogue-detection pon-ports <WORD>`	This will show the rogue detection enabled state.
`(OcNOS)#show pon onu rogue`	This will show the suspected rogue ONUs.
`(OcNOS)#show pon onu isolated`	This will show the isolated rogue ONUs.
`(config-pon)#exit`	Exit configuration mode.

Validation

This section shows the command(s) and output(s) to validate the configuration.

To enable the rogue ONU configuration

```
OcNOS(config-pon)#onu-rogue-detection pon-port pon0/0/1
OcNOS(config-pon)#onu-rogue-detection pon-port pon0/0/2

OcNOS(config-pon)#
```

To isolate the rogue ONU

```
OcNOS(config-pon)# onu isolate serial-number 4252434D12345678 pon-port pon0/0/1
OcNOS(config-pon)#
```

To remove the ONU isolation

```
OcNOS(config-pon)#no onu isolate serial-number 4252434D12345678 pon-port pon0/0/1
```

Execute the show commands to verify the output.

```
OcNOS#sh pon olt 0
  admin-status:   UP
  oper-status:    UP
  onu-mode:       AUTOMATIC_PROVISION
  dhcp-mode:      OFF
  pon-ports:
    (Reason Code: AD - Admin Down
                  DV - DDM Violation
                  PD - Protocol/Port Down)

    PON-PORT-NAME  ADMIN-STATUS  OPER-STATUS  REASON  SPEED  ROGUE-DET
    ------------------------------------------------------------------
    pon0/0/1       UP            UP           -       XG-S   ON
OcNOS#show pon onu-rogue-detection pon-ports
  pon0/0/1
  pon0/0/2
OcNOS#
OcNOS#show pon onu rogue
  Serial Number(Vendor)   PON port        Count
  ---------------------------------------------
  -                       pon0/0/1        1

OcNOS#show pon onu isolated
  Serial Number(Vendor)   PON port
  ---------------------------------
  4252434D12345678(BRCM)  pon0/0/1
OcNOS#
```

CHAPTER 17 ONU Autofinding Configuration

Overview.

ONU Autofinding feature lists the serial numbers of ONU's which are unprovisioned.

Note: Works only in manual provisioning mode.

AsxVolt16:

```
OcNOS(config-pon)#olt-id 0
OcNOS(config-pon-olt)#onu-provisioning-type manual administrative-state up
```

TIBIT

`#configure terminal`	Enter configure mode.
`(config)#pon-configuration`	Enter PON configure mode.
`(config-pon)# olt-id 0`	Configure olt-Identifier.
`(config-pon-olt)# serial-number e8:b4:70:70:01:92`	Serial number for OLT.
`(config-pon-olt)# onu-provisioning-type manual administrative-state up`	Configure manual ONU provisioning type & Enable OLT admin state.
`(config-pon-olt)#exit`	Exit pon olt configure mode.
`#configure terminal`	Enter configure mode.

Validation

This section shows the command(s) and output(s) to validate the configuration.

Execute the `show` command to verify the output.

```
OcNOS#sh pon onu unprovisioned
  OLT-ID     PON-PORT     SERIAL#
  ------------------------------
  0          pon0/0/1     4246575300123130(BFWS00123130)
  0          pon0/0/1     414C5048E3BB8815(ALPHE3BB8815)
```

CHAPTER 18 Firmware Upgrade for Remote OLT (TIBIT)

Overview

OLT must provide a way to list down the firmware images on the four banks of TIBIT. User can copy the image to secondary bank than the active bank. Boot/reset the TIBIT MicroPlug from the specific bank after downloading the image.

To download firmware image and reboot follow the below commands.

`#configure terminal`	Enter configure mode.
`(config)#pon-configuration`	Configure PON parameters.
`(config-pon)# olt firmware-install olt-id 0 bank 0 file:///root/R1.3.0-OLT-FW.bin`	To download firmware image in bank 0.
`(config-pon)# olt reboot olt-id 0 bank 0`	To boot/reset the tibit microplug from specific bank.
`(config-pon-flow-acl)#exit`	Exit pon flow acl configure mode.

Validation

This section shows the command(s) and output(s) to validate the configuration.

Execute the `show` command to verify the output.

Check the existing firmware on the OLT

```
OcNOS# show pon olt 0 firmware-info
    BANK  |VERSION  |SHA      |DATE                      |ACTIVE  |NEXT-ACTIVE
    ------------------------------------------------------------------
    0     |R1.2.0   |3cba51d  |Fri Feb 28 00:18:40 2020 |        |
    1     |R1.2.0   |3cba51d  |Fri Feb 28 00:18:40 2020 |*       |*
    2     |R1.2.0   |3cba51d  |Fri Feb 28 00:18:40 2020 |        |
    3     |R1.3.0   |de6b297  |Thu May 28 23:53:59 2020 |        |
```

After downloading the firmware image on bank 0

```
OcNOS#do show pon olt 0 firmware-info
    BANK  |VERSION  |SHA      |DATE                      |ACTIVE  |NEXT-ACTIVE
    ------------------------------------------------------------------
    0     |R1.3.0   |de6b297  |Thu May 28 23:53:59 2020 |        |*
    1     |R1.2.0   |3cba51d  |Fri Feb 28 00:18:40 2020 |*       |
    2     |R1.2.0   |3cba51d  |Fri Feb 28 00:18:40 2020 |        |
    3     |R1.3.0   |de6b297  |Thu May 28 23:53:59 2020 |        |
```

After reboot

```
OcNOS#show pon olt 0 firmware-info
    BANK  |VERSION  |SHA      |DATE                      |ACTIVE  |NEXT-ACTIVE
    ------------------------------------------------------------------
    0     |R1.3.0   |de6b297  |Thu May 28 23:53:59 2020 |*       |*
    1     |R1.2.0   |3cba51d  |Fri Feb 28 00:18:40 2020 |        |
```

```
2     |R1.2.0   |3cba51d  |Fri Feb 28 00:18:40 2020 |        |
3     |R1.3.0   |de6b297  |Thu May 28 23:53:59 2020 |        |
```

CHAPTER 19 FEC Enable/Disable Configuration

Overview

OLT enable downstream FEC per PON port by default. After Enabling upstream FEC OLT must be able to show the status of upstream FEC per ONU. To configure FEC execute the following commands. Edgecore platform will support enable/disable per ONU whereas TIBIT will keep the upstream FEC enabled by default.

FEC Enable/Disable

Execute the following commands to enable or disable the TC layer encryption.

`#configure terminal`	Enter configure mode.
`(config)#pon-configuration`	Configure PON parameters.
`OcNOS(config-pon)# onu-id <onu-id>`	Input ONU Identifier.
`OcNOS(config-pon-onu)# upstream-fec on`	To Enable the FEC.
`OcNOS(config-pon-onu)# upstream-fec off`	To Disable the FEC.
`OcNOS# show pon statistics onu <onu-id> fec`	To display the FEC statistics.

Validation

This section shows the command(s) and output(s) to validate the configuration.

Enable/Disable the FEC on ASXvOLT-16.

Enable the FEC

```
OcNOS(config)#pon
OcNOS(config-pon)# onu-id 2
OcNOS(config-pon-onu)#  upstream-fec on
```

Disable the FEC

```
OcNOS(config)#pon
OcNOS(config-pon)# onu-id 2
OcNOS(config-pon-onu)#  upstream-fec off
```

Show command for FEC statistics

```
OcNOS#sh pon statistics onu 2 fec

PON port = pon0/0/1 ONU_ID = 2
      codewords      corrected_bytes  codewords_corrected   uncorrectable
-------------------------------------------------------------------------
     1590347974                  816                 1202               2
OcNOS#
```

ONU Status when FEC is ON

```
OcNOS# show pon onu 2
  pon-port-name:     pon0/0/1
  olt-id:            0
  serial#:           414C5048E3BB87DE(ALPHE3BB87DE)
  onu-profile-name:  onup1
  admin-state:       UP
  oper-status:       UP
  encryption:        OFF
  upstream-fec:      ON
  uni-ports:         5
```

Optical Line Termination Command Reference

Contents

This document contains these chapters:

CHAPTER 1 Entering PON configuration Mode

This chapter contains commands for Entering PON configuration.

debug pon all

Use this command to enable debugging of PON module and OMCI stack.

Use the no parameter with this command to disable PON debugging.

Note: This enables POND and SM (State Machine).

Command Syntax

```
debug pon all
no debug pon all
```

Parameters

None

Default

By default, debug command is disabled.

Command Mode

PON configuration mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
OcNOS (config-pon) #debug pon all
```

pon-configuration

Use this command to enter the PON configuration mode.

Command Syntax

```
pon-configuration
```

Parameters

None

Command Mode

Configuration mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
OcNOS(config)#pon-configuration
OcNOS(config-pon)#
```

CHAPTER 2 Translation Profile Commands

This chapter contains commands for Translation Profile.

classification

Use this command to setup matching parameters for translation

Command Syntax

```
classification
```

Parameters

None

Default

None

Command Mode

PON TP mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
(config-pon)#translation-profile profile-name tp1
(config-pon-tp)#classification
(config-pon-tp-classification)#vlan-type tagged vlan-id 3 p-bits 3
(config-pon-tp-classification)#exit
(config-pon-tp)#treatment
(config-pon-tp-treatment)#p-bits 3 operation remove-vlan
(config-pon-tp-treatment)#exit
(config-pon-tp)#exit
(config-pon)#no translation-profile profile-name tp1
(config-pon)#
```

p-bits

Use this command to indicate the translated p-bit and operation.

Command Syntax

```
p-bits <0-7> operation (none | remove-vlan)
```

Parameter

`<0-7>`	P-bits range
`none`	No action, only for vlan-type: untagged
`remove-vlan`	Remove matching VLAN, only for vlan-type:tagged/priorityTagged.

Command Mode

PON TP treatment mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
(config-pon)#translation-profile profile-name tp1
(config-pon-tp)#classification
(config-pon-tp-classification)#vlan-type tagged vlan-id 3 p-bits 3
(config-pon-tp-classification)#exit
(config-pon-tp)#treatment
(config-pon-tp-treatment)#p-bits 3 operation remove-vlan
(config-pon-tp-treatment)#exit
(config-pon-tp)#exit
(config-pon)#no translation-profile profile-name tp1
(config-pon)#
```

translation-profile

Use this command to setup the P-BIT & VLAN translation profile. Note that both tp-classification and tp-treatment must be set to complete tp configuration as illustrated in the example. However, they can be updated individually.

Use the no parameter to delete the translation profile with the specified profile name.

Command Syntax

```
translation-profile profile-name WORD
no translation-profile profile-name WORD
```

Parameter

`profile-name`	Indicate the `profile-name`
`WORD`	Translation Profile name

Default

None

Command Mode

PON Configuration mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
(config-pon)#translation-profile profile-name tp1
(config-pon-tp)#classification
(config-pon-tp-classification)#vlan-type tagged vlan-id 3 p-bits 3
(config-pon-tp-classification)#exit
(config-pon-tp)#treatment
(config-pon-tp-treatment)#p-bits 3 operation remove-vlan
(config-pon-tp-treatment)#exit
(config-pon-tp)#exit
(config-pon)#no translation-profile profile-name tp1
(config-pon)#
```

treatment

Use this command to setup the treatment parameters for translation.

Command Syntax

```
treatment
```

Parameter

None

Command Mode

PON TP mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
(config-pon)#translation-profile profile-name tp1
(config-pon-tp)#classification
(config-pon-tp-classification)#vlan-type tagged vlan-id 3 p-bits 3
(config-pon-tp-classification)#exit
(config-pon-tp)#treatment
(config-pon-tp-treatment)#p-bits 3 operation remove-vlan
(config-pon-tp-treatment)#exit
(config-pon-tp)#exit
(config-pon)#no translation-profile profile-name tp1
(config-pon)#
```

vlan-type

Use this command to setup matching parameters for translation

Command Syntax

```
vlan-type untagged
vlan-type tagged vlan-id < 2-4094> p-bits <0-7>
Vlan-type prioritytagged p-bits <0-7>
```

Parameters

`vlan-id`	Indicate the VLAN Id to match as translation criteria
`<2-4094>`	VLAN Identifier range
`vlan-type`	Indicate the matching criteria for VLAN
`untagged`	Untagged VLAN, no vlan-id
`tagged`	Tagged VLAN, vlan-id is <2-4094>
`priority`	Tagged Priority tagged VLAN, vlan-id is 0
`p-bits`	Indicate the p-bits parameter
`<0-7>`	P-bits range

Default

None

Command Mode

PON TP classification mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
(config-pon)#translation-profile profile-name tp1
(config-pon-tp)#classification
(config-pon-tp-classification)#vlan-type tagged vlan-id 3 p-bits 3
(config-pon-tp-classification)#exit
(config-pon-tp)#treatment
(config-pon-tp-treatment)#p-bits 3 operation remove-vlan
(config-pon-tp-treatment)#exit
(config-pon-tp)#exit
(config-pon)#no translation-profile profile-name tp1
(config-pon)#
```

CHAPTER 3 QoS Profile Commands

This chapter contains commands for QoS Profile.

cir (PON QP Downstream mode)

Use this command to indicate CIR, PIR, and PBS parameters for downstream QoS Profile.

Command Syntax

```
cir <1-10000000> <kbps|mbps|gbps> pir <1-10000000> <kbps|mbps|gbps> pbs <1-
  10000000> <kbytes|mbytes|gbytes>
```

Parameter

None

Default

None

Command Mode

PON QP Downstream mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
#configure terminal
(config)#pon-configuration
(config-pon)#qos-profile profile-name qp1
(config-pon-qp)#downstream
(config-pon-qp-downstream)#cir 1000 kbps pir 1200 kbps
(config-pon-qp-downstream)#exit
(config-pon-qp)#
```

cir (PON QP Upstream mode)

Use this command to indicate the CIR and PIR parameters for upstream QoS Profile.

Command Syntax

```
cir < 1-10000000 > <kbps|mbps|gbps> pir < 1-10000000> <kbps|mbps|gbps>
```

Parameters

None

Default

None

Command Mode

PON QP Upstream mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
#OcNOS#configure terminal
OcNOS(config)#pon-configuration
OcNOS(config-pon)#qos-profile profile-name qp1
OcNOS(config-pon-qp)#upstream
OcNOS(config-pon-qp-upstream)#cir 1000 kbps pir 1200 kbps
OcNOS(config-pon-qp-upstream)#exit
OcNOS(config-pon-qp)#
```

downstream

Use this command to setup the downstream parameters for QoS Profile.

Note: Refer the following:

- It is recommended to set the value of cir/pir to ~4%-5% more than desired rate limit to account for the Inter packet gap.
- TIBIT OLT support range of 272Kbytes-1256Kbytes for PBS.

```
OcNOS(config-pon-qp-downstream)#cir ?
<1-10000000> Downstream Committed information rate 1kbps- 10gbps.Set the
value to ~4%-5% more than desired rate limit to account for inter packet gap
OcNOS(config-pon-qp-downstream)#cir 1 kbps pir ?
<1-10000000> Downstream Committed information rate 1kbps- 10gbps.Set the
value to ~4%-5% more than desired rate limit to account for inter packet gap
OcNOS(config-pon-qp-downstream)#cir 1 kbps pir 256 kbps pbs ?
<1-10000000>  Downstream PBS 1Kbytes-10Gbytes
```

Command Syntax

```
downstream
```

Parameter

None

Default

None

Command Mode

PON QP mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
#OcNOS#configure terminal
OcNOS(config)#pon-configuration
OcNOS(config-pon)#qos-profile profile-name qp1
OcNOS(config-pon-qp)#downstream
OcNOS(config-pon-qp-downstream)#cir 1000 kbps pir 1200 kbps pbs 1200 kbytes
OcNOS(config-pon-qp-downstream)#exit
OcNOS(config-pon-qp)#
```

qos-profile

Use this command to setup the QoS profile parameters. Note that both qp-upstream & qp-downstream must be set to complete tp configuration as illustrated in the example. However, they can be updated individually.

Use the no parameter to delete the QoS profile with the specified profile name.

Command Syntax

```
qos-profile profile-name WORD
no qos-profile profile-name WORD
```

Parameter

WORD	Input QoS Profile name

Default

None

Command Mode

PON Configuration mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
#OcNOS#configure terminal
OcNOS(config)#pon-configuration
OcNOS(config-pon)#qos-profile profile-name qp1
OcNOS(config-pon-qp)#downstream
OcNOS(config-pon-qp-downstream)#cir 15 mbps pir 20 mbps pbs 30 mbytes
OcNOS(config-pon-qp-downstream)#exit
OcNOS(config-pon-qp)#upstream
OcNOS(config-pon-qp-upstream)#cir 15 mbps pir 20 mbps
OcNOS(config-pon-qp-upstream)#exit
OcNOS(config-pon-qp)#exit

OcNOS(config-pon)#no qos-profile profile-name qp1
OcNOS(config-pon)#
```

upstream

Use this command to setup the upstream parameters for QoS Profile.

Note: Refer the following:

- CIR/PIR will be rounded to the nearest multiple of 128kbps.
- PIR should be GREATER than CIR by at least 128kbps.

```
OcNOS(config-pon-qp-upstream)#cir 1 kbps pir ?
 <1-10000000> Upstream Peak information rate 1kbps-10Gbps. Should be at
 least 128Kbps more than CIR. Will be rounded to the nearest
 multiple of 128Kbps

 <kbps|mbps|gbps>
  gbps  Specifies the units of gigabits per second
  kbps  Specifies the units of kilobits per second
  mbps  Specifies the units of megabits per second
```

Command Syntax

```
upstream
```

Parameters

None

Default

None

Command Mode

PON QP mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
#OcNOS#configure terminal
OcNOS(config)#pon-configuration
OcNOS(config-pon)#qos-profile profile-name qp1
OcNOS(config-pon-qp)#upstream
OcNOS(config-pon-qp-upstream)#cir 1000 kbps pir 1200 kbps
OcNOS(config-pon-qp-upstream)#exit
OcNOS(config-pon-qp)#
```

CHAPTER 4 ONU Profile Commands

This chapter contains commands for ONU Profile.

gem-port-name (PON OP TCONT mode)

Use this command to setup the gem port name.

Note: Associate only one GEM-Port to one T-Cont for TIBIT OLT.

Command Syntax

```
gem-port-name WORD
```

Parameter

WORD	Input tcont name

Default

None

Command Mode

PON OP TCONT mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
#configure terminal
(config)#pon-configuration
(config-pon)#onu-profile profile-name op1
(config-pon-op)#uni port-id 1
(config-pon-op-uni)#gem-port-name GEM1 p-bits 1 upstream-priority-queue 1
downstream-priority-queue 2
(config-pon-op-uni)#gem-port-name GEM2 p-bits 2 upstream-priority-queue 3
downstream-priority-queue 4
(config-pon-op-uni)#gem-port-name GEM3 p-bits 3 upstream-priority-queue 5
downstream-priority-queue 6
(config-pon-op-uni)#exit
(config-pon-op)#uni port-id 2
(config-pon-op-uni)#gem-port-name GEM4 p-bits 4 upstream-priority-queue 7
downstream-priority-queue 8
(config-pon-op-uni)#gem-port-name GEM5 p-bits 5 upstream-priority-queue 9
downstream-priority-queue 10
(config-pon-op-uni)#gem-port-name GEM6 p-bits 6 upstream-priority-queue 11
downstream-priority-queue 12
(config-pon-op-uni)#exit
(config-pon-op)#t-cont tc1
(config-pon-op-t-cont)#gem-port-name GEM1
(config-pon-op-t-cont)#gem-port-name GEM4
(config-pon-op-t-cont)#exit
(config-pon-op)#t-cont tc2
(config-pon-op-t-cont)#gem-port-name GEM2
(config-pon-op-t-cont)#gem-port-name GEM5
(config-pon-op-t-cont)#exit
(config-pon-op)#t-cont tc3
(config-pon-op-t-cont)#gem-port-name GEM3
(config-pon-op-t-cont)#gem-port-name GEM6
```

```
(config-pon-op-t-cont)#exit
```

gem-port-name (PON OP UNI mode)

Use this command to setup GEM port name.

Command Syntax

```
gem-port-name WORD
```

Parameters

WORD	Indicate the gem port name

Default

None

Command Mode

PON OP UNI mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
#configure terminal
(config)#pon-configuration
(config-pon)#onu-profile profile-name op1
(config-pon-op)#uni port-id 1
(config-pon-op-uni)#gem-port-name GEM1 p-bits 1 upstream-priority-queue 1
downstream-priority-queue 2
(config-pon-op-uni)#gem-port-name GEM2 p-bits 2 upstream-priority-queue 3
downstream-priority-queue 4
(config-pon-op-uni)#gem-port-name GEM3 p-bits 3 upstream-priority-queue 5
downstream-priority-queue 6
(config-pon-op-uni)#exit
(config-pon-op)#uni port-id 2
(config-pon-op-uni)#gem-port-name GEM4 p-bits 4 upstream-priority-queue 7
downstream-priority-queue 8
(config-pon-op-uni)#gem-port-name GEM5 p-bits 5 upstream-priority-queue 9
downstream-priority-queue 10
(config-pon-op-uni)#gem-port-name GEM6 p-bits 6 upstream-priority-queue 11
downstream-priority-queue 12
(config-pon-op-uni)#exit
(config-pon-op)#t-cont tc1
(config-pon-op-t-cont)#gem-port-name GEM1
(config-pon-op-t-cont)#gem-port-name GEM4
(config-pon-op-t-cont)#exit
(config-pon-op)#t-cont tc2
(config-pon-op-t-cont)#gem-port-name GEM2
(config-pon-op-t-cont)#gem-port-name GEM5
(config-pon-op-t-cont)#exit
(config-pon-op)#t-cont tc3
(config-pon-op-t-cont)#gem-port-name GEM3
(config-pon-op-t-cont)#gem-port-name GEM6
(config-pon-op-t-cont)#exit
```

onu-profile

Use this command to setup the ONU profile parameters. Note that op-uni for all uni ports & op-tcont for all tcont identifiers must be set to complete op configurations as illustrated in the example. However, uni & tcont rules can be updated individually.

Use the no parameter to delete the ONU profile with the specified profile name, delete uni port with specified port id or delete t-cont with specified name.

Command Syntax

```
onu-profile profile-name WORD
no onu-profile profile-name WORD
```

Parameter

WORD	Input QoS Profile name

Default

None

Command Mode

PON Configuration mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
#configure terminal
(config)#pon-configuration
(config-pon)#onu-profile profile-name op1
(config-pon-op)#uni port-id 1
(config-pon-op-uni)#gem-port-name GEM1 p-bits 1 upstream-priority-queue 1
downstream-priority-queue 2
(config-pon-op-uni)#gem-port-name GEM2 p-bits 2 upstream-priority-queue 3
downstream-priority-queue 4
(config-pon-op-uni)#gem-port-name GEM3 p-bits 3 upstream-priority-queue 5
downstream-priority-queue 6
(config-pon-op-uni)#exit
(config-pon-op)#uni port-id 2
(config-pon-op-uni)#gem-port-name GEM4 p-bits 4 upstream-priority-queue 7
downstream-priority-queue 8
(config-pon-op-uni)#gem-port-name GEM5 p-bits 5 upstream-priority-queue 9
downstream-priority-queue 10
(config-pon-op-uni)#gem-port-name GEM6 p-bits 6 upstream-priority-queue 11
downstream-priority-queue 12
(config-pon-op-uni)#exit
(config-pon-op)#t-cont tc1
(config-pon-op-t-cont)#gem-port-name GEM1
(config-pon-op-t-cont)#gem-port-name GEM4
(config-pon-op-t-cont)#exit
(config-pon-op)#t-cont tc2
(config-pon-op-t-cont)#gem-port-name GEM2
(config-pon-op-t-cont)#gem-port-name GEM5
```

```
(config-pon-op-t-cont)#exit
(config-pon-op)#t-cont tc3
(config-pon-op-t-cont)#gem-port-name GEM3
(config-pon-op-t-cont)#gem-port-name GEM6
(config-pon-op-t-cont)#exit
```

t-cont

Use this command to setup T-Cont port to GEM port connections for ONU Profile.

Command Syntax

```
tcont WORD
```

Parameter

WORD	Input tcont name

Default

None

Command Mode

PON OP mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
#configure terminal
(config)#pon-configuration
(config-pon)#onu-profile profile-name op1
(config-pon-op)#uni port-id 1
(config-pon-op-uni)#gem-port-name GEM1 p-bits 1 upstream-priority-queue 1
downstream-priority-queue 2
(config-pon-op-uni)#gem-port-name GEM2 p-bits 2 upstream-priority-queue 3
downstream-priority-queue 4
(config-pon-op-uni)#gem-port-name GEM3 p-bits 3 upstream-priority-queue 5
downstream-priority-queue 6
(config-pon-op-uni)#exit
(config-pon-op)#uni port-id 2
(config-pon-op-uni)#gem-port-name GEM4 p-bits 4 upstream-priority-queue 7
downstream-priority-queue 8
(config-pon-op-uni)#gem-port-name GEM5 p-bits 5 upstream-priority-queue 9
downstream-priority-queue 10
(config-pon-op-uni)#gem-port-name GEM6 p-bits 6 upstream-priority-queue 11
downstream-priority-queue 12
(config-pon-op-uni)#exit
(config-pon-op)#t-cont tc1
(config-pon-op-t-cont)#gem-port-name GEM1
(config-pon-op-t-cont)#gem-port-name GEM4
(config-pon-op-t-cont)#exit
(config-pon-op)#t-cont tc2
(config-pon-op-t-cont)#gem-port-name GEM2
(config-pon-op-t-cont)#gem-port-name GEM5
(config-pon-op-t-cont)#exit
(config-pon-op)#t-cont tc3
(config-pon-op-t-cont)#gem-port-name GEM3
(config-pon-op-t-cont)#gem-port-name GEM6
(config-pon-op-t-cont)#exit
```

uni port-id

Use this command to setup UNI port to GEM port connections for ONU Profile.

Command Syntax

```
uni port-id <0-255>
```

Parameters

port-id	Indicate the port id

Default

None

Command Mode

PON OP mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
#configure terminal
(config)#pon-configuration
(config-pon)#onu-profile profile-name op1
(config-pon-op)#uni port-id 1
(config-pon-op-uni)#gem-port-name GEM1 p-bits 1 upstream-priority-queue 1
downstream-priority-queue 2
(config-pon-op-uni)#gem-port-name GEM2 p-bits 2 upstream-priority-queue 3
downstream-priority-queue 4
(config-pon-op-uni)#gem-port-name GEM3 p-bits 3 upstream-priority-queue 5
downstream-priority-queue 6
(config-pon-op-uni)#exit
(config-pon-op)#uni port-id 2
(config-pon-op-uni)#gem-port-name GEM4 p-bits 4 upstream-priority-queue 7
downstream-priority-queue 8
(config-pon-op-uni)#gem-port-name GEM5 p-bits 5 upstream-priority-queue 9
downstream-priority-queue 10
(config-pon-op-uni)#gem-port-name GEM6 p-bits 6 upstream-priority-queue 11
downstream-priority-queue 12
(config-pon-op-uni)#exit
(config-pon-op)#t-cont tc1
(config-pon-op-t-cont)#gem-port-name GEM1
(config-pon-op-t-cont)#gem-port-name GEM4
(config-pon-op-t-cont)#exit
(config-pon-op)#t-cont tc2
(config-pon-op-t-cont)#gem-port-name GEM2
(config-pon-op-t-cont)#gem-port-name GEM5
(config-pon-op-t-cont)#exit
(config-pon-op)#t-cont tc3
(config-pon-op-t-cont)#gem-port-name GEM3
(config-pon-op-t-cont)#gem-port-name GEM6
(config-pon-op-t-cont)#exit
```

CHAPTER 5 OLT Commands

This chapter contains commands for OLT.

dhcp

Use this command to setup the DHCP relay Option 82 parameter.

Command Syntax

```
dhcp (off | on)
```

Parameter

off	No DHCP relay Option 82 processing
on	DHCP relay Option 82 processing

Default

None

Command Mode

PON OLT mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
#configure terminal
(config)#pon-configuration
(config-pon)#olt-id 1
(config-pon-olt)#onu-provisioning-type manual administrative-state up
(config-pon-olt)#dhcp on
(config-pon-olt)# exit
(config-pon)
```

encryption

Use this command to change encryption state on/off.

Note: Encryption state can be changed on OLT cli level on TIBIT VM.

Command Syntax

```
encryption(on|off)
```

Parameter

off	The encryption is disabled
on	The encryption is enabled

Default

Encryption state is disabled by default.

Command Mode

PON OLT mode on TIBIT VM, and PON ONU on ASXvOLT16

Applicability

This command was introduced in OcNOS-SP version 4.0.

Example

```
#config terminal
(config)#pon
(config-pon)#olt-id 30
(config-pon-olt)#serial-number e8b47070013e
(config-pon-olt)#encryption on
(config-pon-olt)#onu-provisioning-type automatic administrative-state up
(config-pon-olt)#end
```

key-time

Use this command to change a key exchange interval.

Note: The change can happen before and after the OLT configuration. 'show running-config' shall reflect the new value.

Command Syntax

```
key-time <10-3600>   - ASXvOLT16
key-time <60-3600>   - Tibit
```

Parameter

<10-3600>	Number of seconds (ASXvOLT16)
<60-3600>	Number of seconds (Tibit)

Default

Default key-time value is 60 and will not show in 'show running-config'.

Command Mode

PON OLT mode

Applicability

This command was introduced in OcNOS-SP version 4.0.

Example

```
#config terminal
(config)#pon
(config-pon)#olt-id 30
(config-pon-olt)#serial-number e8b47070013e
(config-pon-olt)#key-time 100
(config-pon-olt)#onu-provisioning-type automatic administrative-state up
(config-pon-olt)#end
```

olt firmware-install

Use this command to install firmware on TIBIT microplug.

User can specify which bank to install the firmware with this command, TIBIT microplug can hold up to four different firmwares in its banks. A new firmware can not be installed on Active or Next Active bank. On successful installation, the next active bank is set to the newly installed firmware bank. For microplug to boot from Next Active bank requires a reboot of OLT.

Command Syntax

```
olt firmware-install olt-id <0-63> bank <0-3> URL
```

Parameter

<0-63>	Olt on which firmware will be installed
<0-3>	Olt bank on which firmware will be installed. Cannot be Active or Next Active bank
URL	A file system path where to get firmware binary. file://mnt/usb/path/to/file/<firmware.bin>

Default

None

Command Mode

PON OLT mode

Applicability

This command was introduced in OcNOS-SP version 4.0.

Example

```
#configure pon terminal
OcNOS(config-pon)#do show pon olt 0 firmware-info
    BANK  |VERSION  |SHA      |DATE                     |ACTIVE  |NEXT-ACTIVE
    ------------------------------------------------------------------
    0     |R1.3.0   |de6b297  |Thu May 28 23:53:59 2020 |*       |*
    1     |R1.3.0   |de6b297  |Thu May 28 23:53:59 2020 |        |
    2     |R1.2.1   |fa23467  |Fri Mar  6 22:03:25 2020 |        |
    3     |R1.2.1   |fa23467  |Fri Mar  6 22:03:25 2020 |        |
OcNOS(config-pon)#olt firmware-install olt-id 0 bank 1 file:///home/ocnos/
R1.2.0-OLT-FW.bin
OcNOS(config-pon)#do show pon olt 0 firmware-info
    BANK  |VERSION  |SHA      |DATE                     |ACTIVE  |NEXT-ACTIVE
    ------------------------------------------------------------------
    0     |R1.3.0   |de6b297  |Thu May 28 23:53:59 2020 |*       |
    1     |R1.2.0   |3cba51d  |Fri Feb 28 00:18:40 2020 |        |*
    2     |R1.2.1   |fa23467  |Fri Mar  6 22:03:25 2020 |        |
    3     |R1.2.1   |fa23467  |Fri Mar  6 22:03:25 2020 |        |
OcNOS(config-pon)#olt reboot olt-id 0
OcNOS(config-pon)#do show pon olt 0 firmware-info     BANK  |VERSION  |SHA
|DATE                     |ACTIVE  |NEXT-ACTIVE     -------------------------
-------------------------------------     0     |R1.3.0   |de6b297  |Thu May
28 23:53:59 2020 |        |     1     |R1.2.0   |3cba51d  |Fri Feb 28 00:18:40
```

```
2020 |*       |*     2     |R1.2.1   |fa23467  |Fri Mar  6 22:03:25 2020 |
|      3     |R1.2.1   |fa23467  |Fri Mar  6 22:03:25 2020 |         |
```

olt-id

Use this command to setup the OLT parameters like ONU Provisioning type, OLT Administrative State and DHCP Relay Option 82 state.

Note: Supports single OLT for ASXvOLT16 and the TIBIT OLT supports 0-63 range for OLT-ID.

Use no prefix to delete OLT on TIBIT OLT only.

Command Syntax

```
olt-id <0-65535>
no olt-id <0-63>
```

Parameter

<0-65535>	Input OLT identifier value (For future use)
<0-63>	Input OLT identifier for TIBIT OLT

Default

None

Command Mode

PON Configuration mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
#configure terminal
(config)#pon-configuration
(config-pon)#olt-id 1
(config-pon-olt)#onu-provisioning-type manual administrative-state up
(config-pon-olt)#dhcp on
(config-pon-olt)# exit
(config-pon)
```

olt reboot

Use this command to reboot a specific OLT in TIBIT VM. If no bank is specified, microplug boots with Next Active bank.

Command Syntax

```
olt reboot olt-id <0-63> (bank <0-3>)
```

Parameter

<0-63>	Input OLT identifier value
<0-3>	Input bank value

Default

None

Command Mode

PON Configuration mode

Applicability

This command was introduced in OcNOS-SP version 3.1 and changed in OcNOS-SP version 4.0.

Example

```
#configure terminal
(config)#pon-configuration
(config-pon-olt)# olt reboot olt-id 0

Reboot OLT with firmware in bank 1:
#configure terminal
(config)#pon-configuration
(config-pon-olt)# olt reboot olt-id 0 bank 1
```

onu-provisioning-type

Use this command to setup the ONU Provisioning type parameter.

Note: ONU provisioning mode can be changed dynamically from automatic to manual or from manual to automatic only on TIBIT OLT.

Command Syntax

```
onu-provisioning-type (manual|automatic)administrative-state (disable|enable)
```

Parameter

`manual`	All ONUs connecting to OLT are manual provisioned
`automatic`	All ONUs connecting to OLT are automatic provisioned
`disable`	The OLT is disabled
`enable`	Input OLT is enabed

Default

None

Command Mode

PON OLT mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
#configure terminal
(config)#pon-configuration
(config-pon)#olt-id 1
(config-pon-olt)#onu-provisioning-type manual administrative-state up
(config-pon-olt)#dhcp on
(config-pon-olt)# exit
(config-pon)
```

CHAPTER 6 ONU Commands

This chapter contains commands for ONU.

administrative-state

Use this command to lock or unlock the UNI port.

Command Syntax

```
administrative-state <lock | unlock>
```

Parameter

`lock`	To lock UNI port
`unlock`	To unlock UNI port

Default

None

Command Mode

PON ONU UNI mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
OcNOS#configure terminal
OcNOS(config)#pon-configuration
OcNOS(config-pon)#onu-id 1
OcNOS(config-pon-onu)#olt olt-id 1 port-name pon0/0/1 serial-number
ABCD12AC34BC
onu-profile-name op1
OcNOS(config-pon-onu)#uni-port-id 1
OcNOS(config-pon-onu-uni)#administrative-state unlock
OcNOS(config-pon-onu-uni)#exit
OcNOS(config-pon-onu)#uni-port-id 2
OcNOS(config-pon-onu-uni)#administrative-state unlock
OcNOS(config-pon-onu-uni)#exit
OcNOS(config-pon-onu)#exit
OcNOS(config-pon)#no onu-id 1
```

clear pon onu rogue

Use this command to clear Rogue suspect data for an ONU or PON port.

Command Syntax

```
clear pon onu rogue onu serial-number WORD
clear pon onu rogue pon-port WORD
```

Parameter

WORD	Input Serial number identifier value
WORD	Input pon port value

Default

None

Command Mode

EXEC Mode

Applicability

This command was introduced in OcNOS-SP version 4.0.

Example

```
OcNOS#clear pon onu rogue onu serial-number ABCD12345678
OcNOS#clear pon onu rogue pon-port pon0/0/1
```

disable/enable

Use this command to disable or enable the ONU.

Command Syntax

```
disable
enable
```

Parameters

`disable`	Disable the ONU
`enable`	Enable the ONU

Default

None

Command Mode

PON ONU mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
OcNOS#configure terminal
OcNOS(config)#pon-configuration
OcNOS(config-pon)#onu-id 1
OcNOS(config-pon-onu)disable
OcNOS(config-pon-onu)enable
```

encryption

Use this command to enable/disable TC layer encryption on ASXvOLT16.

Command Syntax

```
encryption <on/off>
```

Parameters

on	Encryption ON
off	Encryption OFF

Default

Encryption is disabled by default.

Command Mode

PON ONU mode on ASXvOLT16.

Applicability

This command was introduced in OcNOS-SP version 4.0.

Examples

```
#config terminal
(config)#pon
(config-pon)#olt-id 30
(config-pon-olt)#onu-provisioning-type automatic administrative-state up
(config-pon-olt)#onu-id 0
(config-pon-onu)#encryption on
```

mtu

Use this command to set maximum packet size value for the UNI port.

Command Syntax

```
mtu <576-8986>
```

Parameters

<576-8986>	MTU range

Default

The default value is 1518.

Command Mode

PON ONU mode on ASXvOLT16.

Applicability

This command was introduced in OcNOS-SP version 4.0.

Examples

```
OcNOS#configure terminal
OcNOS(config)#pon-configuration
OcNOS(config-pon)#onu-id 1
OcNOS(config-pon-onu)#olt olt-id 1 port-name pon0/0/1 serial-number
ABCD12AC34BC
onu-profile-name op1
OcNOS(config-pon-onu)#uni-port-id 1
OcNOS(config-pon-onu-uni)#mtu 6000
OcNOS(config-pon-onu-uni)#exit
OcNOS(config-pon-onu)#exit
OcNOS(config-pon)#no onu-id 1
```

olt olt-id

Use this command to setup the ONU identifier parameter.

Command Syntax

```
olt olt-id <0-65535> pon-port WORD serial-number WORD onu-profile-name WORD
```

Parameter

<0-65535>	Input ONU identifier value
WORD	Input pon port value
WORD	Input serial number identifier value
WORD	Input ONU profile name value

Default

None

Command Mode

PON ONU mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
OcNOS#configure terminal
OcNOS(config)#pon-configuration
OcNOS(config-pon)#onu-id 1
OcNOS(config-pon-onu)#olt olt-id 1 port-name pon0/0/1 serial-number
ABCD12AC34BC
onu-profile-name op1
OcNOS(config-pon-onu)#uni-port-id 1
OcNOS(config-pon-onu-uni)#administrative-state unlock
OcNOS(config-pon-onu-uni)#exit
OcNOS(config-pon-onu)#uni-port-id 2
OcNOS(config-pon-onu-uni)#administrative-state unlock
OcNOS(config-pon-onu-uni)#exit
OcNOS(config-pon-onu)#exit
OcNOS(config-pon)#no onu-id 1
OcNOS(config-pon)#
```

onu isolate

Use this command to isolate ONU.

Use the no form of this command to de-isolate ONU.

Command Syntax

```
onu isolate serial-number WORD (pon-port WORD |)
```

Parameter

WORD	Input Serial number identifier value
WORD	Input PON port value

Default

None

Command Mode

PON Configuration mode

Applicability

This command was introduced in OcNOS-SP version 4.0.

Example

```
OcNOS(config-pon)#onu isolate serial-number ABCD12345678 pon-port pon0/0/1
OcNOS(config-pon)#no onu isolate serial-number ABCD12345678
```

onu mibreset

Use this command to launch mibreset for the ONU.

Command Syntax

```
onu mibreset onu-id <0-4095>
```

Parameter

`<0-4095>`	Input ONU identifier value for mibreset

Default

None

Command Mode

PON Configuration mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
OcNOS(config-pon)#onu mibreset onu-id 0
```

onu reboot

Use this command to reboot the ONU.

Command Syntax

```
onu reboot onu-id <0-4095>
```

Parameter

<0-4095>	Input ONU identifier value to reboot

Default

None

Command Mode

PON Configuration mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
OcNOS(config-pon)#onu reboot onu-id 0
```

onu-id

Use this command to setup the ONU. It includes parameters to specify the connected OLT, the connected PON port, serial number of ONU and translation profile associated with the ONU. The UNI submenu is to configure each UNI port of the ONU.

Use the no parameter to delete ONU with specific ONU Identifier.

Command Syntax

```
onu-id <0-4095>
no onu-id <0-4095>
```

Parameter

<0-4095>	Input ONU identifier value

Default

None

Command Mode

PON Configuration mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
OcNOS#configure terminal
OcNOS(config)#pon-configuration
OcNOS(config-pon)#onu-id 1
OcNOS(config-pon-onu)#olt olt-id 1 port-name pon0/0/1 serial-number
ABCD12AC34BC onu-profile-name op1
OcNOS(config-pon-onu)#uni-port-id 1
OcNOS(config-pon-onu-uni)#administrative-state unlock
OcNOS(config-pon-onu-uni)#exit
OcNOS(config-pon-onu)#uni-port-id 2
OcNOS(config-pon-onu-uni)#administrative-state unlock
OcNOS(config-pon-onu-uni)#exit
OcNOS(config-pon-onu)#exit
OcNOS(config-pon)#no onu-id 1
OcNOS(config-pon)#
```

onu-profile-name

Use this command to change the ONU profile name associated with the ONU.

Command Syntax

```
onu-profile-name WORD force-delete-flows <yes | no>
```

Parameter

WORD	Input ONU profile name
yes	Delete dependent flows
no	Do not delete dependent flows

Default

None

Command Mode

PON ONU mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
OcNOS(config-pon)#onu-id 1
OcNOS(config-pon-onu)#onu-profile-name op1 force-delete-flows yes
```

uni-port-id

Use this command to setup the UNI ports for ONU.

Command Syntax

```
uni-port-id <0-255>
```

Parameter

<0-255>	Input UNI identifier value

Default

None

Command Mode

PON ONU mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
OcNOS#configure terminal
OcNOS(config)#pon-configuration
OcNOS(config-pon)#onu-id 1
OcNOS(onu)#olt olt-id 1 port-name pon0/0/1 serial-number ABCD12AC34BC
onu-profile-name op1
OcNOS(config-pon-onu)#uni-port-id 1
OcNOS(config-pon-onu-uni)#administrative-state unlock
OcNOS(config-pon-onu-uni)#exit
OcNOS(config-pon-onu)#uni-port-id 2
OcNOS(config-pon-onu-uni)#administrative-state unlock
OcNOS(config-pon-onu-uni)#exit
OcNOS(config-pon-onu)#exit
OcNOS(config-pon)#no onu-id 1
OcNOS(config-pon)#
```

upstream-fec

Use this command to change upstream-fec on ASXvOLT16.

Command Syntax

```
upstream-fec <on/off>
```

Parameter

on	FEC ON
off	FEC OFF

Default

FEC is enabled by default.

Command Mode

PON ONU mode on ASXvOLT16

Applicability

This command was introduced in OcNOS-SP version 4.0.

Example

```
#config terminal
(config)#pon
(config-pon)#olt-id 30
(config-pon-olt)#onu-provisioning-type automatic administrative-state up
(config-pon-olt)#onu-id 0
(config-pon-onu)#upstream-fec off
```

CHAPTER 7 Flow Commands

This chapter contains commands for Flow:

dump acl trap

Use this command to dump trapped packets to the file of /tmp/pon_acl_trap_dump.pcap.

Command Syntax

```
dump acl trap enable (flow-id <0-65535> |) (acl-id <0-65535> |) (direction
  (upstream|downstream) |) (limit <1-4000>|)
```

Parameter

`dump acl trap enable`	Command to dump ACL trap enable
`flow-id`	Flow identifier to dump
`<0-65535>`	Flow identifier value
`acl-id`	ACL rule identifier
`<0-65535>`	Input ACL rule identifier value
`direction`	Indicate direction to apply ACL rule
`upstream`	ACL rule to be applied in upstream direction
`downstream`	ACL rule to be applied in downstream direction
`limit`	Size in MB of packet data to trap for matching rule
`<1-4000>`	Input size in MB of packet data to dump value

Default

flow-id: any flow that has trap ACLs if not set

acl-id: any PON trap ACL rule if not set

Direction: both downstream and upstream directions if not set

Limit: 10MB if not set (1MB = 1024 * 1024)

Command Mode

PON Configuration mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
OcNOS#configure terminal
OcNOS(config)#pon-configuration
OcNOS(config-pon)#dump acl trap enable
OcNOS(config-pon)#exit
OcNOS(config)#

OcNOS(config-pon)#no dump acl trap enable

OcNOS#configure terminal
OcNOS(config)#pon-configuration
OcNOS(config-pon)#dump acl trap enable flow-id 1 direction upstream limit 4
OcNOS(config-pon)#exit
```

```
OcNOS(config)#

OcNOS#configure terminal
OcNOS(config)#pon-configuration
OcNOS(config-pon)#dump acl trap enable flow-id 1 acl-id 1 limit 4
OcNOS(config-pon)#exit
OcNOS(config)#
```

flow-id

Use this command to setup the Subscriber Service flows. It consists of UNI, NNI, QoS and ACL submenus.

Use the no parameter to delete the Flow with the specified flow identifier.

Command Syntax

```
flow-id <0-65535>(mode n2one/one2one)
no flow-id <0-65535>
```

Parameter

<0-65535>	Input Flow identifier value
n2one/one2one	Specifies mode of the flow (default mode is one2one)

Default

None

Command Mode

PON Configuration mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
OcNOS#configure terminal
OcNOS(config)#pon-configuration
OcNOS(config-pon)#flow-id 1
OcNOS(config-pon-flow)#uni
OcNOS(config-pon-flow-uni)#onu-id 0 uni-port-id 0 vlan-tag 20 translation-
profile-name tp1
OcNOS(config-pon-flow-uni)#exit
OcNOS(config-pon-flow)#nni
OcNOS(config-pon-flow-nni)#olt-id 1 nni-port-name nni0/0/1 vlan-tag 1
OcNOS(config-pon-flow-nni)#exit
OcNOS(config-pon-flow)#qos
OcNOS(config-pon-flow-qos)#qos-profile-name qp1
OcNOS(config-pon-flow-qos)#exit
OcNOS(config-pon-flow)# exit
OcNOS(config-pon)#no flow-id 1
OcNOS(config-pon)#
```

nni

Use this command to setup NNI parameters of flow. ‘vlan-tag’ is optional parameter.

Command Syntax

```
nni
```

Parameter

None

Default

None

Command Mode

PON Flow mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
OcNOS#configure terminal
OcNOS(config)#pon-configuration
OcNOS(config-pon)#flow-id 1
OcNOS(config-pon-flow)#nni
OcNOS(config-pon-flow-nni)#olt-id 1 nni-port-name nni0/0/1 vlan-tag 1
OcNOS(config-pon-flow-nni)#exit
```

olt-id

Use this command to setup OLT identifier, NNI port name, VLAN tag type and VLAN tag for NNI leg of flow.

Command Syntax

```
olt-id <0-65535> nni-port-name WORD vlan-tag <2-4094>/none (ethertype 0x8100/
  0x88a8)
```

Parameter

`<0-65535>`	Input OLT identifier value for Flow
`WORD`	Input NNI port identifier value for Flow
`<2-4094>`	Input vlan tag identifier for NNI leg of Flow
`0x8100/0x88a8`	Tag Protocol ID for VLAN tag

Default

None

Command Mode

PON Flow NNI mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
OcNOS#configure terminal
OcNOS(config)#pon-configuration
OcNOS(config-pon)#flow-id 1
OcNOS(config-pon-flow)#nni
OcNOS(config-pon-flow-nni)#olt-id 1 nni-port-name nni0/0/1 vlan-tag none
OcNOS(config-pon-flow-nni)#exit
```

onu-id

Use this command to setup the ONU identifier, UNI port identifier, translation profile name, vlan tag type and vlan tag for UNI leg of the flow.

Command Syntax

```
onu-id <0-4095> uni-port-id <0-255> vlan-tag <2-4094> translation-profile-name
  WORD (ethertype 0x88a8)
```

Parameter

`<0-4095>`	Input ONU identifier value for Flow
`<0-255>`	Input uni port identifier value for Flow
`<2-4094>`	Input vlan tag identifier for UNI leg of Flow
`WORD`	Input translation profile name for UNI leg of Flow
`0x88a8`	Replace ETHERTYPE to 0x88a8 for flow

Default

None

Command Mode

PON Flow UNI mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
OcNOS#configure terminal
OcNOS(config)#pon-configuration
OcNOS(config-pon)#flow-id 1
OcNOS(config-pon-flow)#uni
OcNOS(config-pon-flow-uni)#onu-id 1 uni-port-id 1 vlan-tag 3 translation-
profile-name tp1 ethertype 0x88a8
OcNOS(config-pon-flow-uni)#exit
OcNOS(config-pon-flow)#nni
OcNOS(config-pon-flow-nni)#olt-id 1 nni-port-name nni0/0/1 vlan-tag 1
OcNOS(config-pon-flow-nni)#exit
OcNOS(config-pon-flow)#qos
OcNOS(config-pon-flow-qos)#qos-profile-name qp1
OcNOS(config-pon-flow-qos)#exit
OcNOS(config-pon-flow)# exit
OcNOS(config-pon)#no flow-id 1
OcNOS(config-pon)#
```

pon-acl-id

Use this command to setup ACL rules of a subscriber service flow.

Note: The Applicable rule must have priority, action and direction.

Command Syntax

```
pon-acl-id <0-65535> (priority <0-65535>|) (action (allow|drop|trap-to-cpu)|)
  (direction (upstream|downstream)|) (remote-ip (A.B.C.D|X:X::X:X) |) (protocol
  (tcp|udp|any)|) (remote-port <1-65535>|)
```

Parameter

`pon-acl-id`	ACL rule identifier (mandatory)
`<0-65535>`	Input ACL rule identifier value
`priority`	Priority of ACL rule
`<0-65535>`	Input priority value
`action`	Action for packet matching ACL rule
`allow`	Allow matching packets
`drop`	Drop matching packets
`trap-to-cpu`	Trap matching packets to CPU
`direction`	Indicate direction to apply ACL rule
`upstream`	ACL rule to be applied in upstream direction
`downstream`	ACL rule to be applied in downstream direction
`remote-ip`	Downstream source/Upstream destination IP for ACL
`A.B.C.D`	IPv4 address for ACL rule
`X:X::X:X`	IPv6 format for ACL rule
`protocol`	Indicate protocol for ACL rule
`udp`	Apply rule for UDP matching packets
`tcp`	Apply rule for TCP matching packets
`any`	Apply rule for any matching packets
`remote-port`	Downstream source/Upstream destination port for ACL
`<1-65535>`	Value for port

Default

Value not set

Command Mode

PON Flow mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
OcNOS#configure terminal
OcNOS(config)#pon-configuration
OcNOS(config-pon)#flow-id 1
OcNOS(config-pon-flow)#acl
OcNOS(config-pon-flow-acl)# pon-acl-id 1 priority 10 action drop direction
upstream remote-ip 1.2.3.4 protocol tcp remote-port 123
OcNOS(config-pon-flow-acl)# pon-acl-id 2 priority 20 action drop direction
upstream remote-ip 1.2.3.4 protocol udp
OcNOS(config-pon-flow-acl)# pon-acl-id 3 priority 30 action trap-to-cpu
direction upstream remote-ip 1.2.3.5
OcNOS(config-pon-flow-acl)# pon-acl-id 4 priority 29 action allow direction
upstream remote-ip 1.2.3.5 remote-port 123
OcNOS(config-pon-flow-acl)# pon-acl-id 5
OcNOS(config-pon-flow-acl)#no pon-acl-id 1
OcNOS(config-pon-flow-acl)#exit
OcNOS(config-pon-flow)#no acl
OcNOS(config-pon-flow)#
```

qos

Use this command to set the qos profile for the flow.

Command Syntax

```
qos
```

Parameter

None

Default

None

Command Mode

PON Flow mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
OcNOS#configure terminal
OcNOS(config)#pon-configuration
OcNOS(config-pon)#flow-id 1
OcNOS(config-pon-flow)#qos
OcNOS(config-pon-flow-qos)#qos-profile-name qp1
OcNOS(config-pon-flow-qos)#exit
```

qos-profile-name

Use this command to set the qos profile name parameter for the flow.

Command Syntax

```
qos-profile-name WORD
```

Parameter

WORD	Input QOS profile name

Default

None

Command Mode

PON Flow QOS mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
OcNOS#configure terminal
OcNOS(config)#pon-configuration
OcNOS(config-pon)#flow-id 1
OcNOS(config-pon-flow)#qos
OcNOS(config-pon-flow-qos)#qos-profile-name qp1
OcNOS(config-pon-flow-qos)#exit
```

uni

Use this command to setup UNI parameters of flow like ONU identifier and UNI Port identifier. Onu-id passed in the command should present in the onu list. Check “show pon onu brief” or “show running-config" for configured ONU.

Command Syntax

```
uni
```

Parameters

None

Default

None

Command Mode

PON Flow mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
OcNOS#configure terminal
OcNOS(config)#pon-configuration
OcNOS(config-pon)#flow-id 1
OcNOS(config-pon-flow)#uni
OcNOS(config-pon-flow-uni)#onu-id 0 uni-port-id 0 vlan-tag 20 translation-
profile-name tp1
OcNOS(config-pon-flow-uni)#exit
```

CHAPTER 8 Port Interface Commands

This chapter describes the port interface commands:

fec on

Use this command to change NNI port FEC for 50g/100g speed

FEC will be disabled automatically when speed changed.

Use no form of this command to disable FEC for NNI port.

Command Syntax

```
fec on
no fec
```

Parameters

None

Command Mode

Interface mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
(config)#interface nni0/0/1
(config-if)#fec on
(config)#interface nni0/0/1
(config-if)#no fec
```

onu-rogue-detection pon-port

Use this command to enable Rogue ONU detection on a PON port.

Use no form of this command to disable Rogue ONU detection on a PON port.

Command Syntax

```
onu-rogue-detection pon-port IFNAME
no onu-rogue-detection pon-port IFNAME
```

Parameters

IFNAME	PON port interface name

Command Mode

Pon Configuration mode

Applicability

This command was introduced in OcNOS-SP version 4.0.

Example

```
OcNOS(config-pon)#onu-rogue-detection pon-port pon0/0/1
OcNOS(config-pon)#no onu-rogue-detection pon-port pon0/0/1
```

speed

Use this command to change NNI port speed.

FEC will be disabled automatically when speed changed.

Use no form of this command to restore the default speed for NNI interface.

Command Syntax

```
speed (40g|50g|100g)
no speed
```

Parameters

100g	100 giga bits
40g	40 giga bits
50g	50 giga bits

Command Mode

Interface mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
(config)#interface nni0/0/1
(config-if)#speed 100g
(config)#interface nni0/0/1
(config-if)#no speed
```

CHAPTER 9 Show PON commands

This chapter describes the Show PON commands:

- show pon onu uni-port brief
- show pon onu-profile
- show pon onu-profile brief
- show pon qos-profile
- show pon qos-profile brief
- show pon statistics dhcp
- show pon statistics dhcp option-82-pkts
- show pon statistics dhcp rx-pkts
- show pon statistics dhcp tx-pkts
- show pon statistics flow
- show pon statistics flow brief
- show pon statistics flow nni-port
- show pon statistics flow nni-port rx-bytes
- show pon statistics flow nni-port rx-drop-pkts
- show pon statistics flow nni-port rx-pkts
- show pon statistics flow nni-port tx-bytes
- show pon statistics flow nni-port tx-drop-pkts
- show pon statistics flow nni-port tx-pkts
- show pon statistics onu encryption
- show pon statistics onu uni-port
- show pon statistics nni-port
- show pon statistics nni-port brief
- show pon statistics nni-port rx-bytes
- show pon statistics nni-port rx-drop-pkts
- show pon statistics nni-port rx-pkts
- show pon statistics nni-port tx-bytes
- show pon statistics nni-port tx-drop-pkts
- show pon statistics pon-port tx-pkts
- show pon statistics onu uni-port
- show pon statistics pon-port
- show pon statistics pon-port brief
- show pon statistics pon-port rx-bytes
- show pon statistics pon-port rx-drop-bytes
- show pon statistics pon-port rx-pkts
- show pon statistics pon-port tx-drop-bytes
- show pon statistics pon-port tx-pkts
- show pon statistics port brief
- show pon translation-profile
- show pon translation-profile brief

show debugging pon

Use this command to show debugging filters for POND.

Command Syntax

```
show debugging pon
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
#sh debugging pon
  PON State Machine debugging: OFF
  PON Task debugging:          OFF
  PON OMCI debugging:          OFF
  PON NSM client debugging:    OFF
```

show pon acl – all flows

Use this command to show all ACL rules of all flows.

NB: The Applicable rule must have priority, action and direction.

Command Syntax

```
show pon acl all
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
>show pon acl all

====================== Flow ID: 1 ======================
 * : to indicate inapplicable rule

 id     priority direction  action      protocol remote-port   remote-ip
 ------------------------------------------------------------------------
 1        10     upstream   drop        tcp      123           1.2.3.4
 2        20     upstream   drop        udp      -             1.2.3.4
 3        30     downstream trap-to-cpu -        -             1.2.3.5
 4        29     downstream allow       -        123           1.2.3.5
 5      * -      -          -           -        -             -
>
```

show pon acl – specific flow

Use this command to show ACL rule(s) of a flow.

NB: The Applicable rule must have priority, action and direction.

Command Syntax

```
show pon acl flowid <0-65536> (aclid <0-65536> |) (downstream|upstream|)
```

Parameters

<0-65535>	Flow Identifier
<0-65535>	ACL Identifier
downstream	Downstream direction
upstream	Upstream direction

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
>show pon acl flowid 1
* : to indicate inapplicable rule
id priority direction action protocol remote-port remote-ip
-----------------------------------------------------------------
1 10 upstream drop tcp 123 1.2.3.4
2 20 upstream drop udp - 1.2.3.4
3 30 downstream trap-to-cpu - - 1.2.3.5
4 29 downstream allow - 123 1.2.3.5
5 * - - - - - -
>show pon acl flowid 1 upstream
* : to indicate inapplicable rule
id priority direction action protocol remote-port remote-ip
-----------------------------------------------------------------
1 10 upstream drop tcp 123 1.2.3.4
2 20 upstream drop udp - 1.2.3.4
>
```

show pon acl – trap dump status

Use this command to show ACL trap dump status.

Command Syntax

```
show pon acl dump trap status
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
>show pon acl dump trap status
 Dump:         Disabled
 Complete:     No
 Limit:        0MB
 wr-size:      0KB
 wr-packets:   0
 drop-packets: 0
 Flow ID:      0
 ACL Rule ID:  0
 Direction:    upstream
>
```

show pon avail-bw pon-port

Use this command to show PON port available upstream bandwith.

Note: This command is applicable for ASXvOLT16 only.

Command Syntax

```
show pon avail-bw pon-port IFNAME
```

Parameters

IFNAME	PON Port name

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
# show pon avail-bw pon-port pon0/0/1
  PON port: pon0/0/1
    CBR_BW(kbps)     TOTAL_BW(kbps)      NEXT_ONU_TOTAL_BW(kbps)
    ------------------------------------------------------------------------------
-----------
    128                       128                               0
```

show pon debug on/off

Use this command to enable/disable POND debugging information filter(s).

Command Syntax

```
show pon debug (pond|state-machine|omci|nsm|all|) on/off
```

Parameters

`all`	POND all information
`nsm`	POND NSM client information
`omci`	POND OMCI information
`pond`	POND task information
`state-machine`	POND State Machine information
`on`	Enable debug information
`off`	Disable debug information

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
#show pon debug omci
% POND OMCI debugging is on
```

show pon flow

Use this command to show details for flow.

Command Syntax

```
show pon flow <0-65535> (extra-info)
```

Parameters

`<0-65535>`	FLOW identifier
`extra-info`	Optionally include extra information

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
#sh pon flow 100
  flow-oper-status:     UP
  pon-port:             pon0/0/1
  uni-end:
    onu-id:             0

```

show pon flow brief

Use this command to show all flows.

Command Syntax

```
show pon flow brief
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
#show pon flow brief
    FLOW-ID       FLOW-OPER-STATUS
    ------------------------------
    17            UP
    19            UP
```

show pon license

Use this command to show current license information on TIBIT VM.

Command Syntax

```
show pon license
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.1.

Example

```
#show pon license
-----------------------------------------------
PON License Information
-----------------------------------------------
Maximum Licenses     : 8
Available Licenses   : 6
Used Licenses        : 2
```

show pon olt

Use this command to show parameters for configured OLT with particular OLT ID.

Command Syntax

```
show pon olt <0-65535>
```

Parameters

<0-65535>	OLT identifier

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
#sh pon olt 0
  admin-status:   UP
  oper-status:    UP
  onu-mode:       AUTOMATIC_PROVISION
  dhcp-mode:      OFF
  pon-ports:
    (Reason Code: AD - Admin Down
                  DV - DDM Violation
                  PD - Protocol/Port Down)

    PON-PORT-NAME  ADMIN-STATUS  OPER-STATUS  REASON  SPEED
    ------------------------------------------------------------
    pon0/0/1       UP            UP           -       XG-S
    pon0/0/2       DOWN          DOWN         AD      XG-S
    pon0/1/3       DOWN          DOWN         AD      XG-S
    pon0/1/4       DOWN          DOWN         AD      XG-S
    pon0/2/5       DOWN          DOWN         AD      XG-S
    pon0/2/6       DOWN          DOWN         AD      XG-S
    pon0/3/7       DOWN          DOWN         AD      XG-S
    pon0/3/8       DOWN          DOWN         AD      XG-S
    pon0/4/9       DOWN          DOWN         AD      XG-S
    pon0/4/10      DOWN          DOWN         AD      XG-S
    pon0/5/11      DOWN          DOWN         AD      XG-S

    pon0/7/16      DOWN          DOWN         AD      XG-S
  nni-ports:
    (Reason Code: AD - Admin Down
                  DV - DDM Violation
```

```
                PD - Protocol/Port Down)

    NNI-PORT-NAME  ADMIN-STATUS  OPER-STATUS  REASON  SPEED  FEC
    ------------------------------------------------------------
    nni0/0/1       UP            UP           -       40G    OFF
    nni0/0/2       UP            DOWN         PD      40G    OFF
    nni0/0/3       UP            DOWN         PD      40G    OFF
    nni0/0/4       UP            DOWN         PD      100G   OFF
```

show pon olt administrative-status

Use this command to show administrative status for configured OLT.

Command Syntax

```
show pon olt <0-65535> adminstrative-status
```

Parameters

`<0-65535>`	OLT identifier

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
>show pon olt 0 adminstrative-status
admin-status: UP
```

show pon olt brief

Use this command to show all configured OLTs.

Command Syntax

```
show pon olt brief
```

Parameters

None

Default

None

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
>show pon olt brief
  OLT-ID           ADMIN-STATUS       OPER-STATUS
  ---------------------------------------------
  0                UP                 UP
```

show pon olt mapping

Use this command to show all discovered OLTs.

Command Syntax

```
show pon olt mapping
```

Parameters

None

Default

None

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.1.

Examples

```
>show pon olt mapping
Codes: UA - Unassigned
   UNMAPPED OLTs
   OLT-ID          SERIAL
   ----------------------
   UA          e8:b4:70:70:01:3e
```

show pon olt nni-port

Use this command to show specific NNI port for configured OLT.

Command Syntax

```
show pon olt <0-65535> nni-ports WORD
```

Parameters

`<0-65535>`	OLT identifier.
`WORD`	NNI port name.

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
#sh pon olt 0 nni-port nni0/0/1
admin-state:   UP
oper-status:   UP
speed:         40G
fec:           OFF
```

show pon olt nni-port brief

Use this command to show NNI prots for configured OLT.

Command Syntax

```
show pon olt <0-65535> nni-port brief
```

Parameters

<0-65535>	OLT identifier.

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
#sh pon olt 0 nni-port brief
    (Reason Code: AD - Admin Down
                  DV - DDM Violation
                  PD - Protocol/Port Down)

    NNI-PORT-NAME  ADMIN-STATUS  OPER-STATUS  REASON  SPEED  FEC
    ------------------------------------------------------------
    nni0/0/1       UP            UP           -       40G    OFF
    nni0/0/2       UP            DOWN         PD      40G    OFF
    nni0/0/3       UP            DOWN         PD      40G    OFF
    nni0/0/4       UP            DOWN         PD      100G   OFF
```

show pon olt pon-port

Use this command to show specific PON port for configured OLT.

Command Syntax

```
show pon olt <0-65535> pon-port WORD
```

Parameters

`<0-65535>`	OLT identifier.
`WORD`	PON port name.

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
#sh pon olt 0 pon-port pon0/0/1
admin-state:   UP
oper-status:   UP
speed:         XG-S
```

show pon olt pon-port brief

Use this command to show PON ports for configured OLT.

Command Syntax

```
show pon olt <0-65535> pon-port brief
```

Parameters

<0-65535>	OLT identifier.

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
#sh pon olt 0 pon-port brief
    (Reason Code: AD - Admin Down
                  DV - DDM Violation
                  PD - Protocol/Port Down)

    PON-PORT-NAME  ADMIN-STATUS  OPER-STATUS  REASON  SPEED
    ------------------------------------------------------
    pon0/0/1       UP            UP           -       XG-S
    pon0/0/2       DOWN          DOWN         AD      XG-S
    pon0/1/3       DOWN          DOWN         AD      XG-S

    pon0/5/12      DOWN          DOWN         AD      XG-S
    pon0/6/13      DOWN          DOWN         AD      XG-S
    pon0/6/14      DOWN          DOWN         AD      XG-S
    pon0/7/15      DOWN          DOWN         AD      XG-S
    pon0/7/16      DOWN          DOWN         AD      XG-S
```

show pon onu

Use this command to show configuration parameters of ONU.

Command syntax

```
show pon onu <0-4095>
```

Parameters

<0-4095>	ONU identifier.

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
#sh pon onu 0
  pon-port-name:     pon0/0/1
  olt-id:            0
  serial#:           414C5048E3BB8AF9(ALPHE3BB8AF9)
  onu-profile-name:  default_onu_profile
  admin-state:       UP
  oper-status:       UP
  uni-ports:         5
  tcont-maps:
    ALLOC-ID      TCONT-NAME            PON-PORT-NAME
    ------------------------------------------------
    1025          default_tcont         pon0/0/1
  gem-port-maps:
    GEM-PORT-ID   GEM-PORT-NAME         PON-PORT-NAME
    ------------------------------------------------
    1025          default_gemport       pon0/0/1
  onu-flow-list:
    FLOW-ID       FLOW-OPER-STATUS
    ------------------------------
    100           UP
  onu-uni-list:
    UNI-PORT-ID   ADMIN-STATUS  OPER-STATUS   CONFIG-IND
    ------------------------------------------------------
    0             UNLOCKED      ENABLED       1G Ethernet full duplex
```

show pon onu admin-status

Use this command to show admin status for configured ONU.

Command Syntax

```
show pon onu <0-4095> admin-status
```

Parameters

`<0-4095>`	ONU identifier.

Default

None

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
#sh pon onu 0 admin-state
admin-state: UP
```

show pon onu ani-port-power-level

Use this command to show power level on ANI port.

Command Syntax

```
show pon onu <0-4095> ani-port-power-level
```

Parameters

<0-4095>	ONU identifier

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
#sh pon onu 0 ani-port-power-level
  ANI-PORT-ID   OPTICAL-SIGNAL-LEVEL(dBm)
  ---------------------------------------
  1             -19.100
```

show pon onu auto finding

Use this command to show all un-provisioned ONUs on different PON ports.

Command Syntax

```
show pon onu unprovisioned
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 4.0.

Example

```
#show pon onu unprovisioned
  OLT-ID     PON-PORT     SERIAL#
  -------------------------------
  30         pon30/0/1    49534B5471E81090(ISKT71E81090)
```

show pon onu brief

Use this command to list all configured ONUs.

Command Syntax

```
show pon onu brief
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
#sh pon onu brief
  ONU-ID     OLT-ID   ADMIN-STATE OPER-STATUS     PON-PORT     SERIAL#
  ------------------------------------------------------------------------
  0          0        UP          UP              pon0/0/1
414C5048E3BB8AF9(ALPHE3BB8AF9)
  1          0        UP          UP              pon0/0/1
414C5048E3931006(ALPHE3931006)
```

show pon onu isolated

Use this command to show isolated ONUs on different PON ports. Isolated ONUs remain in isolation list even after reboot.

Command Syntax

```
show pon onu isolated
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 4.0.

Example

```
OcNOS#show pon onu isolated ?
  |  Output modifiers
  >  Output redirection
  <cr>

OcNOS#show pon onu isolated
 Serial Number(Vendor)   PON port
 ---------------------------------
 4142434412345678(ABCD)  pon0/0/1
```

show pon onu mib-audit

Use this command to check MIBs sync between OLT and ONU.

Command Syntax

```
show pon onu <0-4095> mib-audit
```

Parameters

<0-4095>	ONU identifier

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
#sh pon onu 0 mib-audit
  MIB-DATA-SYNC-ONU  MIB-DATA-SYNC-OLT  MIB-AUDIT-RESULT
  ------------------------------------------------------
  54                 54                 SYNCED
```

show pon onu olt-id

Use this command to show OLT connected to configured ONU.

Command Syntax

```
show pon onu <0-4095> olt-id
```

Parameters

`<0-4095>`	ONU identifier

Default

By default, there is no domain password.

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
>show pon onu 0 olt-id
olt-id: 0
```

show pon onu olt-pon-port

Use this command to show OLT's PON port connected to configured ONU.

Command Syntax

```
show pon onu <0-4095> olt-pon-port
```

Parameters

`<0-4095>`	ONU identifier.

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
>show pon onu 0 olt-pon-port
pon-port-name: pon0/0/1
```

show pon onu onu-profile-name

Use this command to show ONU profile linked to configured ONU.

Command Syntax

```
show pon onu <0-4095> onu-profile-name
```

Parameters

`<0-4095>` ONU identifier

Defaults

None

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
>show pon onu 0 onu-profile-name
onu-profile-name: profile1--1234
```

show pon onu operational-status

Use this command to show operational status for configured ONU.

Command Syntax

```
show pon onu <0-4095> operational-status
```

Parameters

`<0-4095>`	ONU identifier.

Default

None

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

The following example shows setting the administrative distance for all routes.

```
>show pon onu 0 operational-status
oper-status: UP
```

show pon onu queries

Use this command to show ONU queries sent to specific ONU device.

Command Syntax

```
show pon onu <0-4095> queries
```

Parameters

`<0-4095>`	Flow Identifier

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

None

show pon onu query brief

Use this command to show all queries sent to all available ONUs.

Command Syntax

```
show pon onu query brief
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

None

show pon onu rogue

Use this command to show suspected rogue ONUs on different PON ports.

Command Syntax

```
show pon onu rogue
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 4.0.

Examples

```
# OcNOS#show pon onu rogue ?
  |  Output modifiers
  >  Output redirection
  <cr>

OcNOS#show pon onu rogue
  Serial Number(Vendor)   PON port        Count
  ----------------------------------------------
  -                       pon0/0/1        53
```

show pon onu tcont

Use this command to show details of a T-Cont and the UNI ports & GEM ports connections.

Command Syntax

```
show pon onu <0-4095> tcont WORD
```

Parameters

`<0-4095>` ONU identifier

`WORD` T-CONT name

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
#sh pon onu 1111 tcont tcont1-1--234
  gem-ports:
    GEM-PORT-NAME        UNI-PORT-ID   P-BITS   US-PQ   DS-PQ
    ------------------------------------------------------------
    gemport1-1-1-1234    1             3        2       1
    gemport1-1-2--1234   1             3        2       1
```

show pon onu tcont brief

Use this command to show details of all T-Cont and the UNI ports & GEM ports connections.

Command Syntax

```
show pon onu <0-4095> tcont brief
```

Parameters

<0-4095>	ONU identifier

Default

Exec mode

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
#sh pon onu 1111 tcont brief
  ====================================
  | T-CONT-NAME: tcont1-1--234         |
  ====================================
  gem-ports:
    GEM-PORT-NAME        UNI-PORT-ID   P-BITS   US-PQ   DS-PQ
    ------------------------------------------------------------
    gemport1-1-1-1234    1             3        2       1
    gemport1-1-2--1234   1             3        2       1
  ====================================
  | T-CONT-NAME: tcont1-2----1234      |
  ====================================
  gem-ports:
    GEM-PORT-NAME        UNI-PORT-ID   P-BITS   US-PQ   DS-PQ
    ------------------------------------------------------------
    gemport1-2-1-1234    2             3        2       1
    gemport1-2-2-11      2             3        2       1
```

show pon onu tcont gem-port

Use this command to show parameters of a GEM Port.

Command Syntax

```
show pon onu <0-4095> tcont WORD gem-port WORD
```

Parameters

`<0-4095>`	ONU identifier.
`WORD`	T-CONT name
`WORD`	GEM-PORT name

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
#sh pon onu 1111 tcont tcont1-1--234 gem-port gemport1-1-1-1234
    GEM-PORT-NAME        UNI-PORT-ID   P-BITS   US-PQ   DS-PQ
    ------------------------------------------------------
    gemport1-1-1-1234    1             3        2       1
```

show pon onu uni-port

Use this command to show details of a specific UNI port.

Command Syntax

```
show pon onu <0-4095> uni-port <0-255>
```

Parameters

<0-4095>	ONU identifier
<0-255>	UNI port identifier

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

```
Example
#sh pon onu 0 uni-port 0
  UNI-PORT-ID   ADMIN-STATUS  OPER-STATUS   CONFIG-IND
  ------------------------------------------------
  0             UNLOCKED      ENABLED       1G Ethernet full duplex
```

show pon onu uni-port brief

Use this command to show details of a UNI ports for ONU.

Command Syntax

```
show pon onu <0-4095> uni-port brief
```

Parameters

<0-4095>	ONU identifier

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
#sh pon onu 0 uni-port brief
  num-of-unis               : 5
  upstream-priority-queues  : 8
  downstream-priority-queues: 8
  onu-uni-list:
    UNI-PORT-ID   ADMIN-STATUS  OPER-STATUS   CONFIG-IND
    ---------------------------------------------------
    0             UNLOCKED      ENABLED       1G Ethernet full duplex
```

show pon onu-profile

Use this command to show particular configured ONU profile and its parameters.

Command Syntax

```
show pon onu-profile  WORD
```

Parameters

WORD	Translation profile name

Default

None

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
#sh pon onu-profile onu2_profile-99999999
  ready-status: READY
  onu-tconts:
    T-CONT-NAME
    -----------
    tcont2-1--1234
    tcont2-2
  gem-ports:
    GEM-PORT-NAME        TCONT-NAME           UNI-PORT-ID   P-BITS   US-PQ   DS-PQ
    ------------------------------------------------------------------------------
    gemport2-1-1--12     tcont2-1--1234       1             0        0       0
    gemport2-1-2         tcont2-1--1234       1             1        1       1
    gemport2-2-1-13      tcont2-2             1             2        2       2
    gemport2-2-2         tcont2-2             1             3        3       3
  uni-logic-ports:
    UNI-LOGIC-PORT-ID:
    ------------------
    1
```

show pon onu-profile brief

Use this command to show all configured ONU profiles.

Command Syntax

```
show pon onu-profile brief
```

Parameters

None

Default

By default, the area password is not configured

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
>show pon onu-profile brief
  default-onu-profile
  profile1--1234
  profile2-99999999
```

show pon qos-profile

Use this command to show particular configured QoS profile and its parameters.

Command Syntax

```
show pon qos-profile WORD
```

Parameters

WORD	QOS profile name.

Default

None

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
#sh pon qos-profile qosprofile1-12323
  *CIR - Committed Information Rate
  *PIR - Peak Information Rate
  *PBS - Peak Burst Size

  dn-stream-rate-policer:
    CIR      CIR_UNITS      PIR      PIR_UNITS      PBS      PBS_UNITS
    ------------------------------------------------------------------
    11       mbps           2        mbps           2        mbytes
  up-stream-rate-policer:
    CIR      CIR_UNITS      PIR      PIR_UNITS
    ---------------------------------------
    1        mbps           2        mbps
```

show pon qos-profile brief

Use this command to show all configured QoS profiles and their parameters.

Command Syntax

```
show pon qos-profile brief
```

Parameters

None

Default

None

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
#sh pon qos-profile brief
default_qos_profile
qosprofile1-12323
qosprofile2---12323
```

show pon statistics dhcp

Use this command to show all DHCP statistics.

Command Syntax

```
show pon statistics dhcp
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
>show pon statistics dhcp
  DHCPDISCOVER                    :  0
  DHCPOFFER                       :  0
  DHCPREQUEST                     :  0
  DHCPDECLINE                     :  0
  DHCPACK                         :  0
  DHCPNAK                         :  0
  DHCPRELEASE                     :  0
  DHCPINFORM                      :  0
  DHCPV6_SOLICIT                  :  0
  DHCPV6_ADVERTISE                :  0
  DHCPV6_REQUEST                  :  0
  DHCPV6_CONFIRM                  :  0
  DHCPV6_CONFIRM                  :  0
  DHCPV6_RENEW                    :  0
  DHCPV6_REBIND                   :  0
  DHCPV6_REPLY                    :  0
  DHCPV6_RELEASE                  :  0
  DHCPV6_DECLINE                  :  0
  DHCPV6_RECONFIGURE              :  0
  DHCPV6_INFORMATION_REQUEST      :  0
  DHCP_INVALID_REQ                :  0
  DHCP_INVALID_RES                :  0
  DHCP_INVALID_V6                 :  0
  DHCP_PKT_RCV                    :  0
  DHCP_PKT_RCV_ERROR              :  0
  DHCP_PKT_SENT                   :  0
  DHCP_PKT_SEND_ERROR             :  0
  DHCP_OPTION82_INSERTED          :  0
  DHCP_OPTION82_REMOVED           :  0
  DHCP_OPTION82_INSERTION_ERROR   :  0
  DHCP_OPTION82_DELETION_ERROR    :  0
  DHCP_INVALID_PACKET             :  0
  DHCP_FLOW_NOT_FOUND             :  0
  DHCP_IF_NOT_FOUND               :  0
```

show pon statistics dhcp option-82-pkts

Use this command to show DHCP option-82 statistics.

Command Syntax

```
show pon statistics dhcp option-82-pkts
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS version 1.3.

Example

```
>show pon statistics dhcp option-82-pkts
  DHCP Option-82 statistics:
    INSERTED        REMOVED         INSERTION-ERROR   DELETION-ERROR
    ------------------------------------------------------------------
    0               0               0                 0
```

show pon statistics dhcp rx-pkts

Use this command to show received DHCP packets number.

Command Syntax

```
show pon statistics dhcp rx-pkts
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
>show pon statistics dhcp rx-pkts
DHCP rx packets: 0
```

show pon statistics dhcp tx-pkts

Use this command to show transmitted DHCP packets number.

Command Syntax

```
show pon statistics dhcp tx-pkts
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
>show pon statistics dhcp tx-pkts
DHCP tx packets: 0
```

show pon statistics flow

Use this command to show statistics per specific flow. Note that the port statistics for ports associated with flow displays aggregated statistics of port (aggregating stats for all flows associated with the port).

Command Syntax

```
show pon statistics flow <0-65535>
```

Parameters

<0-65535>	Flow Identifier

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
#sh pon statistics flow 100
  NNI port: nni0/0/1 Aggregated
    RX-PKTS     RX-BYTES      TX-PKTS     TX-BYTES      RX-DROP-PKT TX-DROP-PKT
    ------------------------------------------------------------------------
    1113        183743        363         66458         0           0
  UNI port: 0, ONU-ID: 0 Aggregated
    PACKETS         BYTES           DIRECTION
    ----------------------------------------
    363             63554           UPSTREAM
    8               680             DOWNSTREAM
```

show pon statistics flow brief

Use this command to show all flows statistics. Note that the port statistics for ports associated with flow displays aggregated statistics of port (aggregating stats for all flows associated with the port).

Command Syntax

```
show pon statistics flow brief
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
#sh pon statistics flow brief
  ======================
  | FLOW-ID: 100        |
  ======================
  NNI port: nni0/0/1 Aggregated
    RX-PKTS     RX-BYTES      TX-PKTS     TX-BYTES      RX-DROP-PKT TX-DROP-PKT
    ------------------------------------------------------------------------
    1090        179937        363         66458         0           0
  UNI port: 0, ONU-ID: 0 Aggregated
    PACKETS         BYTES           DIRECTION
    ----------------------------------------
    363             63554           UPSTREAM
    8               680             DOWNSTREAM
```

show pon statistics flow nni-port

Use this command to show statistics for nni-port in specific flow. Note that the port statistics for ports associated with flow displays aggregated statistics of port (aggregating stats for all flows associated with the port).

Command Syntax

```
show pon statistics flow <0-65535> nni-port
```

Parameters

<0-65535>	Flow Identifier

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
#sh pon statistics flow 100 nni-port
  NNI port: nni0/0/1 Aggregated
    RX-PKTS     RX-BYTES      TX-PKTS     TX-BYTES      RX-DROP-PKT TX-DROP-PKT
    ------------------------------------------------------------------------
    1138        188049        385         70562         0           0
```

show pon statistics flow nni-port rx-bytes

Use this command to show received bytes for nni-port in specific flow. Note that the port statistics for ports associated with flow displays aggregated statistics of port (aggregating stats for all flows associated with the port).

Command Syntax

```
show pon statistics flow <0-65535> nni-port rx-bytes
```

Parameters

`<0-65535>`	Flow Identifier

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
#sh pon statistics flow 100 nni-port rx-bytes
  (aggregated) bytes:   195874
```

show pon statistics flow nni-port rx-drop-pkts

Use this command to show rx dropped packets for nni-port in specific flow. Note that the port statistics for ports associated with flow displays aggregated statistics of port (aggregating stats for all flows associated with the port).

Command Syntax

```
show pon statistics flow <0-65535> nni-port rx-drop-pkts
```

Parameters

`<0-65535>`	Flow Identifier

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
#sh pon statistics flow 100 nni-port rx-drop-pkts
  (aggregated) dropped packets: 0
```

show pon statistics flow nni-port rx-pkts

Use this command to show received packets for nni-port in specific flow. Note that the port statistics for ports associated with flow displays aggregated statistics of port (aggregating stats for all flows associated with the port).

Command Syntax

```
show pon statistics flow <0-65535> nni-port rx-pkts
```

Parameters

`<0-65535>`	Flow Identifier

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
#sh pon statistics flow 100 nni-port rx-pkts
  (aggregated) packets: 1157
```

show pon statistics flow nni-port tx-bytes

Use this command to show transmitted bytes for nni-port in specific flow. Note that the port statistics for ports associated with flow displays aggregated statistics of port (aggregating stats for all flows associated with the port).

Command Syntax

```
show pon statistics flow <0-65535> nni-port tx-bytes
```

Parameters

`<0-65535>`	Flow Identifier

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
#sh pon statistics flow 100 nni-port tx-bytes
  (aggregated) bytes:   81864
```

show pon statistics flow nni-port tx-drop-pkts

Use this command to show tx dropped packets for nni-port in specific flow. Note that the port statistics for ports associated with flow displays aggregated statistics of port (aggregating stats for all flows associated with the port).

Command Syntax

```
show pon statistics flow <0-65535> nni-port tx-drop-pkts
```

Parameters

`<0-65535>`	Flow Identifier

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
#sh pon statistics flow 100 nni-port tx-drop-pkts
  (aggregated) dropped packets: 0
```

show pon statistics flow nni-port tx-pkts

Use this command to show transmitted packets for nni-port in specific flow. Note that the port statistics for ports associated with flow displays aggregated statistics of port (aggregating stats for all flows associated with the port).

Command Syntax

```
show pon statistics flow <0-65535> nni-port tx-pkts
```

Parameters

<0-65535>	Flow Identifier

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
#sh pon statistics flow 100 nni-port tx-pkts
  (aggregated) packets: 425
```

show pon statistics onu encryption

Use this command to show encryption stats for a specific ONU in a system.

Note: This command is applicable on TIBIT VM.

Command Syntax

```
show pon statistics onu <0-65535> encryption
```

Parameters

<0-65535>	ONU id

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 4.0.

Examples

```
OcNOS#show pon statistics onu 0 encryption

PON port = pon0/0/1 ONU_ID = 0
        encrypted_bytes  encrypted_pkts          plain_bytes      plain_pkts
-------------------------------------------------------------------------------
TX                16224             338                    0               0
RX                    0               0                16512             344
```

show pon statistics flow uni-port

Use this command to show UNI port Tx,Rx statistics for specific flow. Note that the port statistics for ports associated with flow displays aggregated statistics of port (aggregating stats for all flows associated with the port).

Command Syntax

```
show pon statistics flow <0-65535> uni-port
```

Parameters

<0-65535>	Flow Identifier

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
#sh pon statistics flow 100 uni-port
  UNI port: 0, ONU-ID: 0 Aggregated
    PACKETS         BYTES           DIRECTION
    ----------------------------------------
    456             80228           UPSTREAM
    8               680             DOWNSTREAM
```

show pon statistics nni-port

Use this command to show stats per specific NNI port.

Command Syntax

```
show pon statistics nni-port IFNAME
```

Parameters

IFNAME	NNI Port name

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
#sh pon statistics nni-port nni0/0/1
  NNI port: nni0/0/1
    RX-PKTS     RX-BYTES      TX-PKTS     TX-BYTES      RX-DROP-PKT TX-DROP-PKT
    ------------------------------------------------------------------------
    981         161919        271         49394         0           0
```

show pon statistics nni-port brief

Use this command to show stats for all NNI ports in a system.

Command Syntax

```
show pon statistics nni-port brief
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
#show pon statistics nni-port brief
  NNI port: nni0/0/1
    RX-PKTS     RX-BYTES      TX-PKTS     TX-BYTES      RX-DROP-PKT TX-DROP-PKT
    ------------------------------------------------------------------------
    915         151076        197         35726         0           0
  NNI port: nni0/0/2
    RX-PKTS     RX-BYTES      TX-PKTS     TX-BYTES      RX-DROP-PKT TX-DROP-PKT
    ------------------------------------------------------------------------
    0           0             0           0             0           0
  NNI port: nni0/0/3
    RX-PKTS     RX-BYTES      TX-PKTS     TX-BYTES      RX-DROP-PKT TX-DROP-PKT
    ------------------------------------------------------------------------
    0           0             0           0             0           0
  NNI port: nni0/0/4
    RX-PKTS     RX-BYTES      TX-PKTS     TX-BYTES      RX-DROP-PKT TX-DROP-PKT
    ------------------------------------------------------------------------
    0           0             0           0             0           0
```

show pon statistics nni-port rx-bytes

Use this command to show number of received bytes for specific NNI port.

Command Syntax

```
show pon statistics nni-port IFNAME rx-bytes
```

Parameters

IFNAME	NNI Port name

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
>show pon statistics nni-port nni0/0/1 rx-bytes
Rx bytes:   1001
```

show pon statistics nni-port rx-drop-pkts

Use this command to show number of rx dropped packets for specific NNI port.

Command Syntax

```
show pon statistics nni-port IFNAME rx-drop-pkts
```

Parameters

IFNAME	NNI Port name

Default

By default, max-lsp-lifetime is set to 1200 seconds.

Command Mode

None

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
>show pon statistics nni-port nni0/0/1 rx-drop-pkts
Rx dropped packtes:   0
```

show pon statistics nni-port rx-pkts

Use this command to show number of received packets for specific NNI port.

Command Syntax

```
show pon statistics nni-port IFNAME rx-pkts
```

Parameters

IFNAME	NNI Port name

Command Mode

Exec mod

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
>show pon statistics nni-port nni0/0/1 rx-pkts
Rx packets: 101
```

show pon statistics nni-port tx-bytes

Use this command to show number of transmitted bytes for specific NNI port.

Command Syntax

```
show pon statistics nni-port IFNAME tx-bytes
```

Parameters

IFNAME	NNI Port name

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
>show pon statistics nni-port nni0/0/1 tx-bytes
Tx bytes:   2001
```

show pon statistics nni-port tx-drop-pkts

Use this command to show number of tx dropped packets for specific NNI port.

Command Syntax

```
show pon statistics nni-port IFNAME tx-drop-pkts
```

Parameters

IFNAME	NNI Port name

Default

By default, the maximum number of areas is 3.

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
>show pon statistics nni-port nni0/0/1 tx-drop-pkts
Tx dropped packtes:   2001
```

show pon statistics nni-port tx-pkts

Use this command to show number of transmitted packets for specific NNI port.

Command Syntax

```
show pon statistics nni-port IFNAME tx-pkts
```

Parameters

IFNAME	NNI Port name

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
>show pon statistics nni-port nni0/0/1 tx-pkts
Tx packets: 201
```

show pon statistics onu uni-port

Use this command to show Tx,Rx statistics on specific UNI port.

Command Syntax

```
show pon statistics onu <0-4095> uni-port <0-255>
```

Parameters

<0-4095>	ONU Identifier
<0-255>	UNI Port identifier

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
#sh pon statistics onu 0 uni-port 0
  UNI port: 0, ONU-ID: 0
    PACKETS         BYTES           DIRECTION
    ----------------------------------------
    363             63554           UPSTREAM
    8               680             DOWNSTREAM
```

show pon statistics pon-port

Use this command to show stats for specific PON port.

Command Syntax

```
show pon statistics pon-port IFNAME
```

Parameters

IFNAME	PON Port name

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
#show pon statistics pon-port pon0/0/1
  PON port: pon0/0/1
    RX-PKTS     RX-BYTES      TX-PKTS     TX-BYTES      RX-DROP-PKT TX-DROP-PKT
    ------------------------------------------------------------------------
    940         76803         691         33168         0           0
```

show pon statistics pon-port brief

Use this command to show stats for all PON ports in a system.

Command Syntax

```
show pon statistics pon-port brief
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
show pon statistics pon-port brief
  PON port: pon0/0/1
    RX-PKTS     RX-BYTES      TX-PKTS     TX-BYTES      RX-DROP-PKT TX-DROP-PKT
    ------------------------------------------------------------------------
    896         68926         691         33168         0           0
```

show pon statistics pon-port rx-bytes

Use this command to show number of received bytes for specific PON port.

Command Syntax

```
show pon statistics pon-port IFNAME rx-bytes
```

Parameters

IFNAME	PON Port name

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
>show pon statistics pon-port pon0/0/1 rx-bytes
Rx bytes:   1001
```

show pon statistics pon-port rx-drop-bytes

Use this command to show number of droppped rx packets for specific PON port.

Command Syntax

```
show pon statistics pon-port IFNAME rx-drop-pkts
```

Parameters

IFNAME	PON Port name

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
#sh pon statistics pon-port pon0/0/1 rx-drop-pkts
Rx dropped packets: 0
```

show pon statistics pon-port rx-pkts

Use this command to show number of received packets for specific PON port.

Command Syntax

```
show pon statistics ports pon-port IFNAME rx-pkts
```

Parameters

IFNAME	PON Port name

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
>show pon statistics pon-port pon0/0/1 rx-pkts
Rx packets: 101
```

show pon statistics pon-port tx-drop-bytes

Use this command to show number of droppped tx packets for specific PON port.

Command Syntax

```
show pon statistics pon-port IFNAME tx-drop-pkts
```

Parameters

IFNAME	PON Port name

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
#sh pon statistics pon-port pon0/0/1 tx-drop-pkts
Tx dropped packets: 0
```

show pon statistics pon-port tx-pkts

Use this command to show number of transmitted packets for specific PON port.

Command Syntax

```
show pon statistics pon-port IFNAME tx-pkts
```

Parameters

IFNAME	PON Port name

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
>show pon statistics pon-port pon0/0/1 tx-pkts
Tx packets: 201
```

show pon statistics port brief

Use this command to show stats for all ports in a system.

Command Syntax

```
show pon statistics port brief
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
#sh pon statistics port brief
  PON port: pon0/0/1
    RX-PKTS     RX-BYTES      TX-PKTS     TX-BYTES      RX-DROP-PKT TX-DROP-PKT
    ------------------------------------------------------------------------
    875         65260         691         33168         0           0
  NNI port: nni0/0/1
    RX-PKTS     RX-BYTES      TX-PKTS     TX-BYTES      RX-DROP-PKT TX-DROP-PKT
    ------------------------------------------------------------------------
    873         144098        179         32568         0           0
  NNI port: nni0/0/2
    RX-PKTS     RX-BYTES      TX-PKTS     TX-BYTES      RX-DROP-PKT TX-DROP-PKT
    ------------------------------------------------------------------------
    0           0             0           0             0           0
  NNI port: nni0/0/3
    RX-PKTS     RX-BYTES      TX-PKTS     TX-BYTES      RX-DROP-PKT TX-DROP-PKT
    ------------------------------------------------------------------------
    0           0             0           0             0           0
  NNI port: nni0/0/4
    RX-PKTS     RX-BYTES      TX-PKTS     TX-BYTES      RX-DROP-PKT TX-DROP-PKT
    ------------------------------------------------------------------------
    0           0             0           0             0           0
```

show pon translation-profile

Use this command to show specific translation profile.

Command Syntax

```
show pon translation-profile WORD
```

Parameters

WORD	Translation profile name

Default

By default, adjacency-check command is disabled

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
#show pon translation-profile default_translation_profile
 ------------------------------------------------------------------------------
                             |         CLASSIFICATION         |     TREATMENT
 TRANS-PROFILE-NAME          | VLAN-TYPE      VLAN-ID  P-BITS | OPERATION    P-BITS
 ------------------------------------------------------------------------------
 default_translation_profile  UNTAGGED       0        0        NONE         0
#
```

show pon translation-profile brief

Use this command to show all configured translation profiles and their parameter values.

Command Syntax

```
show pon translation-profile brief
```

Parameters

None

Default

By default, adjacency-check command is disabled

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
#show pon translation-profile brief
  default_translation_profile
```

CHAPTER 10 CMM Show Commands

This chapter describes the CMM-Show commands:

show hardware-information transceiver

Use this command to show XFP transceiver presence, tx, rx states.

Note: This command is applicable for ASXvOLT16 only.

Command Syntax

```
show hardware-information transceiver
```

Parameters

None

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
OcNOS#show hardware-information transceiver

TX     : Transmit status
RX-Los : Receive status
RESET  : Normal (Out of reset), Reset (In reset)
POWER  : Power level Low/High
 -     : NotApplicable

SFP:[0-0]
-----------------------------------------------
PORT   PRESENCE        Tx         Rx-Los
-----------------------------------------------

XFP:[1-16]
-----------------------------------------------
PORT   PRESENCE        Tx         Rx-Los
-----------------------------------------------
1      Present         On         Off
2      Not Present     Off        -
3      Not Present     Off        -
4      Not Present     Off        -
5      Not Present     Off        -
6      Not Present     Off        -
7      Not Present     Off        -
8      Not Present     Off        -
9      Not Present     Off        -
10     Not Present     Off        -
11     Not Present     Off        -
12     Not Present     Off        -
```

```
13      Not Present     Off         -
14      Not Present     Off         -
15      Not Present     Off         -
16      Not Present     Off         -
```

show interface controllers

Use this command to show XFP transceiver EEPROM info.

Note: This command is applicable for ASXvOLT16 only.

Command Syntax

```
show interface (IFNAME|) controllers
```

Parameters

IFNAME	Physical Interface Name

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Examples

```
OcNOS#show interface pon0/0/1 controllers
Codes: SMF - Single Mode Fiber, MMF - Multi Mode Fiber, FC - Fiber Channel
       OM1 - 62.5 Micron MMF [200MHz*km @ 850nm & 500MHz*km @ 1310nm]
       OM2 - 50 Micron MMF [500MHz*km @ 850nm & [500MHz*km @ 1310nm]
       OM3 - 50 Micron MMF [2000MHz*km @ 850nm], OUI - Vendor ID
       OM4 - 50 Micron MMF [4700MHz*km @ 850nm], BR - Bit Rate, CC - Check Code
       AOC - Active Optical Cable, ACC -  Active Copper Cable, PC - Power Class
       CDR - Clock Data Recovery, CLEI - Common Language Equipment Identification
       LR - Long Reach, SR - Short Reach, IR - Intermediate Reach
       CCA - Copper Cable Attenuation

Port Number                   : 1

DDM Support                    : Yes
```

show interface transceiver

Use this command to show XFP rx/tx power level, temperature, current and voltage values and alarm thresholds.

Note: This command is applicable for ASXvOLT16 only.

Command Syntax

```
show interface (IFNAME|) transceiver (detail|threshold violations|)
```

Parameters

IFNAME	Physical Interface Name
detail	Transceiver info such as volt,temp,power and current
threshold violations	Threshold violation info

Command Mode

Exec mode

Applicability

This command was introduced in OcNOS-SP version 3.0.

Example

```
OcNOS#show interface pon0/0/1 transceiver detail
Codes:     * Not Supported by device        -- No Power

```

SECTION 19 Glossary

Glossary

Conventions

This document uses the conventions described below.

Sort Order

The terms are arranged in ASCII order with the case of the characters ignored. This is the same as if the terms were sorted by this Linux command:

sort -f

This means that spaces, symbols, and digits come before alphabetic characters. Digits are sorted as strings, not numeric values (“10” comes before “2”).

The exact ASCII collating sequence is as shown below, with a space character in the first position:

```
 !"#$%&'()*+,-./
0123456789:;<=>?@ABCDEFGHIJKLMNOPQRSTUVWXYZ[\]^_`abcdefghijklmnopqrstuvwxyz{|}~
```

There are some exceptions to this rule when it makes more sense than strict ASCII order:

- (S,G) is under S
- G.8032 and G.8032 are under Numbers

Acronyms

The full phrase is shown before the acronym. For example:

- network address translation (NAT)
- Local Area Network (LAN)

An exception is when the acronym is used exclusively to refer to the term, in which case the acronym is shown before the full form:

- I-SID (Service Instance Identifier)
- NETCONF (Network Configuration Protocol)

When an acronym is part of a phrase and is defined separately, its full form is not shown:

- BGP confederation
- FEC-to-NHLFE (FTN) map
- GARP VLAN Registration Protocol (GVRP)
- MAC address

Case

As shown in the examples above, all lowercase is used for terms except when the predominant usage is initial uppercase or all uppercase.

Terms

Numbers

1588v2. IEEE specification for Precision Time Protocol (PTP).

802. A family of IEEE Local Area Network (LAN) standards. The services and protocols specified by the 802 standards map to Layer 1 (L1) and Layer 2 (L2) of the Open Systems Interconnection (OSI) Reference Model:

- 802.1: Overview architecture of LANs and interneworking
- 802.2: The logical link control (LLC) sublayer of Layer 2 (L2)
- 802.3: Layer 1 (L1) and the Media Access Control (MAC) sublayer of Layer 2 (L2), Also called Ethernet.

802.1AB. IEEE specification for Link Layer Discovery Protocol (LLDP).

802.1ad. Amendment to IEEE 802.1Q for Provider Bridging (PB).

802.1ag. Amendment to IEEE 802.1Q for Connectivity Fault Management (CFM).

802.1ah. IEEE specification that adds Provider Backbone Bridging (PBB) to 802.1ad Provider Bridging (PB):

802.1ak. Amendment to IEEE 802.1Q for Multiple Registration Protocol (MRP).

802.1aq. Amendment to IEEE 802.1D for Shortest Path Bridging (SPB).

802.1AX. IEEE specification for link aggregation and Multi-Chassis Link Aggregation (MC-LAG).

802.1D. IEEE specification which allows multiple LANs to be connected together through what the standard calls a “MAC bridge” which filters data sent between LAN segments, allowing networks to be partitioned for administrative purposes and reducing network congestion. The more common term for a MAC bridge is switch. The 802.1D standard includes Spanning Tree Protocol (STP) and Rapid Spanning Tree Protocol (RSTP).

802.1p. IEEE 802.1Q defines priority signaling for traffic that can be used by Quality of Service (QoS) mechanisms to differentiate traffic. Packets are tagged as belonging to a queue, which determines the priority of the packet. Although this technique is often called “802.1p”, there is no standard by that name. Instead, the technique is incorporated into 802.1Q standard.

802.1Q. IEEE Virtual Local Area Network (VLAN) and Multiple Spanning Tree Protocol (MSTP) specifications. This standard refers to VLANs as “virtual bridged networks”. The 802.1D standard covers “VLAN-unaware” switches, while 802.1Q extends 802.1D for “VLAN-aware” switches.

802.1Qau. Amendment to IEEE 802.1Q for Quantized Congestion Notification (QCN).

802.1Qay. Amendment to IEEE 802.1Q for Provider Backbone Bridge-Traffic Engineering (PBB-TE).

802.1Qaz. Amendment to IEEE 802.1Q for Data Center Bridging Capability Exchange (DCBX) and Enhanced Transmission Selection (ETS).

802.1Qbb. Amendment to IEEE 802.1Q for Priority-based Flow Control (PFC).

802.1Qbg. Amendment to IEEE 802.1Q for Edge Virtual Bridging (EVB).

802.1v. Amendment to IEEE 802.1Q to classify incoming packets based on data link layer protocol identification.

802.3ah. IEEE specification for Ethernet to the First Mile (EFM).

802.3x. IEEE specification for flow control.

G.8032. ITU-T specification for Ethernet Linear Protection Switching (ELPS).

G.8032. ITU-T specification for Ethernet Ring Protection Switching (ERPS).

A

Access Control List (ACL). A set of rules used to filter traffic. Each rule specifies a set of conditions (such as source address, destination address, type of packet, or combination of these items) that a packet must meet to match the rule. When a device determines that an ACL applies to a packet, it tests the packet against the conditions of all rules. The first match determines whether the packet is permitted or denied.

access layer. In the network design model, the layer that connects devices such as desktops, laptops, servers, and printers to the network and provides end users access to network resources. This layer accepts traffic into a network and can pass that traffic to the distribution layer. The access layer is usually built using Layer 2 (L2) switching such as Spanning Tree Protocol (STP). This layer connects logical broadcast domains and provides isolation to groups of users. Typically, Virtual Local Area Network (VLAN) instances are implemented as broadcast domains in the access layer. Also called the edge layer. See also customer edge (CE), provider edge (PE).

acknowledgment (ACK). Notification sent from one network device to another to acknowledge that some event (for example, receipt of a message) has occurred.

active route. Route chosen from all routes in a Routing Information Base (RIB) to reach a destination. Active routes are installed in the Forwarding Information Base (FIB).

address. A unique identifier for a device on a network, either as a sender or receiver. An address can be a physical address or a logical address.

See also address family, address resolution, Classless Interdomain Routing (CIDR), domain name, Domain Name Service (DNS), dynamic address, IP address, MAC address, name resolution, static address.

address family. A specific type of network addressing supported by a routing protocol. Examples are IPv4 unicast and IPv4 multicast.

address resolution. The process of translating the address of an entity on one system to the equivalent address of the same entity on another system. For instance, translating an IP address to its Domain Name Service (DNS) name. See also Address Resolution Protocol (ARP).

Address Resolution Protocol (ARP). A Transmission Control Protocol/Internet Protocol (TCP/IP) mechanism that maps a MAC address to an IP address in the ARP cache data structure. Defined in RFC 826. See also Neighbor Discovery Protocol (NDP).

adjacency. The relationship between neighboring devices for exchanging routing information. Adjacent devices share a common network segment.

A given device can have multiple adjacencies, but each adjacency consists of only two devices connected by one link. A protocol data unit (PDU) that goes between them does not have to pass through any other network devices. See also neighbor.

administrative distance. How reliable the source of the route is considered to be. A lower value is preferred over a higher value. An administrative distance of 255 indicates no confidence in the source; routes with this distance are not installed in the Routing Information Base (RIB). Also called route preference.

Advanced Encryption Standard (AES). A cryptographic algorithm for use by U.S. Government organizations to protect sensitive (unclassified) information. Defined in Federal Information Processing Standards (FIPS) PUB 197.

advertising. Process in which routing or service updates are sent at specified intervals so that other devices on the network can maintain lists of usable routes.

Agent Extensibility (AgentX). A protocol used to implement Simple Network Management Protocol (SNMP) that defines communications between an SNMP agent and an SNMP client. AgentX does not directly communicate with an SNMP client, but relies on the agent to handle the protocol details of SNMP. Defined by RFC 2741.

aggregate route. A single entry in a routing table that represents a combination of groups of routes that have common addresses. See also route summarization.

alarm indication signal (AIS). A signal transmitted instead of the normal signal to maintain transmission continuity and to indicate to the receiving device that a transmission interruption (fault) has occurred either at the equipment originating the AIS signal or upstream of that equipment.

American National Standards Institute (ANSI). A voluntary organization of corporate, government, and other members that develops international and U.S. standards relating to, among other things, communications and networking. ANSI is a member of the International Electrotechnical Commission (IEC) and the International Organization for Standardization (ISO).

application-specific integrated circuit (ASIC). An integrated circuit that is designed for a specific application.

area. A logical division of devices that maintains detailed routing information about itself as well as routing information that allows it to reach other routing subdomains. An area divides a network into small, manageable pieces, reducing the amount of information each device must store and maintain about all other devices.

In Intermediate System to Intermediate System (IS-IS) and Open Shortest Path First (OSPF), an area is a set of contiguous networks and hosts within an autonomous system (AS) that have been administratively grouped together.

area border router (ABR). A router on the border of one or more Open Shortest Path First (OSPF) areas that connects those areas to the backbone network. An ABR is a member of both the OSPF backbone and its attached areas. Therefore, an ABR maintains routing tables for both the backbone topology and the topology of the other areas. See also Not-So-Stubby-Area (NSSA), stub area.

authentication. A process that verifies that data is not altered during transmission and ensures that users are communicating with the individual or organization that they believe they are communicating with.

authentication, authorization, and accounting (AAA). A framework for controlling access to computer resources, enforcing policies, auditing usage, and providing the information necessary to bill for services:

- Authentication determines who the user is and whether to grant that user access to the network
- Authorization determines what the user can do
- Accounting tracks the user's activities and provides an audit trail that can be used for billing or resource tracking

See also Lightweight Directory Access Protocol (LDAP), Remote Authentication Dial In User Service (RADIUS), Terminal Access Controller Access Control System Plus (TACACS+).

Authentication Header (AH). An Internet Protocol Security (IPsec) protocol that authenticates either all or part of the contents of a packet by adding a header with a a hash message authentication code (HMAC) calculated based on the values in the packet. AH provides authentication but not confidentiality. See also Encapsulating Security Payload (ESP).

Automatic Protection Switching (APS). A means to detect a signal failure or signal degrade on a working channel and switch traffic to a protection channel. There are two types of APS:

- Ethernet Linear Protection Switching (ELPS)
- Ethernet Ring Protection Switching (ERPS)

autonomous system (AS). A network controlled as a single administrative entity sharing a common routing strategy. An autonomous system is subdivided into areas. An AS runs an Interior Gateway Protocol (IGP) such as Routing Information Protocol (RIP), Open Shortest Path First (OSPF), or Intermediate System to Intermediate System (IS-IS) within its boundaries. An AS uses an Exterior Gateway Protocol (EGP) to exchange routing information with other ASs.

autonomous system border router (ASBR). An area border router (ABR) located between an Open Shortest Path First (OSPF) autonomous system (AS) and a non-OSPF network. ASBRs run both OSPF and another routing protocol, such as Routing Information Protocol (RIP).

An ASBR is a link between the OSPF autonomous system and the outside network. An ASBR exchanges routing information with routers in other ASes. The ASBR redistributes routing information received from other ASs throughout its own AS. An ASBR must reside in a standard OSPF area.

availability. The amount of time that a system is available during time periods when it is expected to be available. Availability is often measured as a percentage of an elapsed year. For example, 99.95% availability equates to 4.38 hours of downtime in a year (0.0005 * 365 * 24=4.38) for a system that is expected to be available all the time.

B

B-MAC. A source and destination backbone MAC address (B-AA and a B-DA) in a Provider Backbone Bridging (PBB) header.

B-TAG. See backbone VLAN (B-VLAN).

backbone. The part of a network used as the primary path for transporting traffic between network segments.

backbone core bridge (BCB). A device that bridges frames based on backbone VLAN (B-VLAN) and backbone MAC address (B-MAC) information in a Provider Backbone Bridging (PBB) network core.

backbone edge bridge (BEB). A device that encapsulates customer frames for transmission across a Provider Backbone Bridging (PBB) network. There are two types:

- B-BEB (B type BEB): Contains a B-component for bridging in the provider space based on backbone MAC address (B-MAC) and backbone VLAN (B-VLAN) information.
- I-BEB (I type BEB): Contains an I-component for bridging in the customer space based on customer MAC address (C-MAC) and service VLAN (S-VLAN) information.

backbone VLAN (B-VLAN). A field in a Provider Backbone Bridging (PBB) header that carries the backbone VLAN identifier information. The format is the same as a service VLAN (S-VLAN) tag. Also called B-VID tag, B-TAG.

backhaul. The part of a hierarchical network that connects small subnetworks at the edge of the network to the core or backbone network.

In wireless backhaul, the part of the network that transports traffic from a cellular base station to a core network that routes and switches voice and data traffic.

bandwidth. A measure of the data transfer rate of a communications transport medium.

base station. An earth-based transmitting/receiving station for cellular phones and other wireless transmission systems.

Bellman-Ford algorithm. Used in distance-vector routing protocols such as Routing Information Protocol (RIP) to determine the best path to all routes in the network. Contrast with Dijkstra algorithm.

best effort. Traffic class in which the network forwards as many packets as possible in as reasonable a time as possible. By default, packets not explicitly assigned to a specific traffic class are assigned to the best-effort class.

BGP confederation. A method to solve scaling problems created by the iBGP full-mesh requirement. BGP confederations effectively break up a large autonomous system (AS) into subautonomous systems (sub-ASs). Each sub-AS must be uniquely identified within the confederation AS by a sub-AS number.

Within a sub-AS, the same iBGP full mesh requirement exists. Connections to other confederations are made with eBGP, and peers outside the sub-AS are treated as external. To avoid routing loops, a sub-AS uses a confederation sequence, which operates like an AS path but uses only the privately assigned sub-AS numbers.

BGP neighbor. Another device on the network that is running Border Gateway Protocol (BGP). There are two types of BGP neighbors: internal neighbors in the same autonomous system (AS) and external neighbors in different autonomous systems.

BGP peer. A remote Border Gateway Protocol (BGP) speaker that is an established neighbor of the local BGP speaker. BGP peers do not have to be directly connected to each other to share a BGP session.

BGP speaker. A router configured to run the Border Gateway Protocol (BGP) routing protocol. A BGP speaker must be explicitly configured with a set of BGP peers with which it exchanges routing information.

Bidirectional Forwarding Detection (BFD). Protocol that reduces the reliance upon the relatively slow hello mechanism in routing protocols to detect failures where no hardware signaling is available. BFD works with Border Gateway Protocol (BGP), Open Shortest Path First (OSPF) v2, and Intermediate System to Intermediate System (IS-IS) to enable them to receive failure notifications. Defined in RFCs 5880 and 5881.

bit error rate (BER). The ratio of error bits to the total number of bits transmitted. A BER is generally shown as a negative exponent (for example, 10-7, which means one out of 10,000,000 bits is in error).

Border Gateway Protocol (BGP). An Exterior Gateway Protocol (EGP) that maintains a table of IP networks, or prefixes, which designate network reachability among autonomous system (AS) instances. BGP uses path-vector routing that makes decisions based on path, network policies, and/or rule sets. BGP is the primary protocol for the global Internet. First defined by RFC 1163.

BGP Version 4 (BGP4) defined in RFC 4271 supports Classless Interdomain Routing (CIDR) and route summarization.

BGP performs these tasks:

- Collects information about reachable networks from neighboring autonomous systems

- Advertises its reachable networks to routers inside the AS and to neighboring autonomous systems
- Selects routes if there are multiple routes available.

Each BGP device can have both external and internal connections to other BGP devices:

- Internal BGP (iBGP) connections are within the same autonomous system
- External BGP (eBGP) connections are between different autonomous systems

The configuration and behavior is slightly different between eBGP and iBGP.

You can use iBGP for multihomed BGP networks (with more than one connection to the same external autonomous system).

To avoid routing loops, iBGP does not advertise routes learned from an internal BGP peer to other internal BGP peers. Instead, BGP requires that all internal peers be fully meshed so that any route advertised by one router is advertised to all peers within the autonomous system (AS). As a network grows, the full-mesh requirement becomes difficult to manage. To combat scaling problems, BGP uses route reflection and BGP confederations.

Multiprotocol BGP (MP-BGP) allows different types of addresses (address families) to be distributed in parallel. MP-BGP supports IPv4 and IPv6 addresses as well as unicast and multicast variants of each. Defined in RFC 4760. See also IPv6 Provider Edge (6PE).

See also community.

bridge. A device operating at Layer 1 (L1) and Layer 2 (L2) of the Open Systems Interconnection (OSI) Reference Model that forwards frames from one network segment to another based on the MAC address.

The term bridge also describes a device that connects collision domains. Collisions that appear on one side of a switch are not allowed to propagate to the other.

Originally, bridges only had two ports, with each one connected to a network segment. Later, bridges had multiple ports that could connect more than two network segments as well as directly connecting hosts. As bridges evolved, they were also able to filter frames, that is, forward only certain traffic from one network segment to another. This type of device is sometimes called an intelligent bridge, but the more modern term is switch. The term “bridge” is somewhat archaic but is still often used in standards documents.

bridge protocol data unit (BPDU). A protocol data unit (PDU) sent by switches running the Spanning Tree Protocol (STP) to learn about other switches in the network and maintain the spanning tree.

broadcast. The process of a single host simultaneously sending the same message to all nodes on a network. Compare to multicast, where a only a subset of the receivers are addressed. See also unicast.

bursty. The tendency of the bandwidth needed in a network to vary greatly from one moment to the next.

C

C-MAC. A source and destination customer MAC address (C-SA and a C-DA) in a Provider Backbone Bridging (PBB) header.

C-TAG. See customer VLAN (C-VLAN).

Carrier Ethernet. Extensions to Ethernet that enable network operators to provide Ethernet services to customers and to use Ethernet technology in their networks. See also Metro Ethernet Forum (MEF).

certificate. Electronic document that identifies a person or entity. Through the use of keys and certificates, the entities exchanging data can authenticate each other.

channel. A connecting path that carries information from a sending device to a receiving device. A channel can refer to a physical medium (such as a coaxial cable or fiber optic cable).

circuit. A communications channel or path between two devices capable of carrying electrical current.

circuit switching. A network where a dedicated circuit must be opened between devices before they can communicate and, while the circuit is open, no other devices may use that circuit or parts of it. A circuit can remain open without any information transmission, and still be unusable by other devices; it must be closed before it is available to other users. Contrast with packet switching.

Class of Service (CoS). A way of managing traffic in a network by grouping similar types of traffic (for example, e-mail, video, voice, file transfer) together and treating each type as a class with its own level of service priority. However, no guarantees are made that a given priority will meet any specified minimum level. See also Quality of Service (QoS).

classful IP addressing. An older addressing scheme for configuring the ratio of networks to hosts using fixed length prefixes. See Classless Interdomain Routing (CIDR).

Classless Interdomain Routing (CIDR). A notation for specifying an IP addresses and its network prefix which appends a slash character to the address and a decimal number indicating the leading bits in the network prefix. For example:

- In the IPv4 notation “192.168.0.0/16”:
  - “192.168” (the first 16 bits) defines the network address.
  - .0.0 up to .255.255 refer to the host addresses on that network. This leaves 16 bits to contain host addresses, enough for 65536 host addresses.
- In the IPv6 notation “2001:db8::/32”:
  - “2001:db8” (the first 32 bits) defines the network address.
  - :0:0:0:0:0:0 to:ffff:ffff:ffff:ffff:ffff:ffff refer to host addresses on that network. This leaves 96 bits to contains host addresses, enough for 7,922,816,251,426,433 host addresses.

The lower the number after the slash, the more hosts contained in that block.

CIDR uses variable length subnet masking (VLSM) based on arbitrary length prefixes. In VLSM, the number of network and host bits assigned to a subnet can vary based on the number of hosts the subnet needs to support.

CIDR replaced traditional classful IP addressing, in which address allocation was based on octet (8-bit) boundary segments of the IP address. In CIDR, the boundary between the network and host portions of an IP address can be on any bit boundary. The old classful A, B, and C network designations correspond to CIDR prefixes of /8, /16, or /24. 192.168.0.0/16 corresponds to an old class B network. With CIDR, finer grained division of networks are possible, down to individual IP addresses, such as 192.168.100.2/32.

CIDR routes can be carried by Open Shortest Path First (OSPF), Intermediate System to Intermediate System (IS-IS), and Routing Information Protocol (RIP).

Before CIDR notation, IPv4 networks were represented using dotted decimal notation for both the address and a subnet mask.

Also called route summarization or supernetting.

client/server architecture. A computing architecture that distributes processing between clients and servers on the network. A client program makes a service request from a server which fulfils the request.

collapsed core. Collapsing the core layer and the distribution layer into one layer (one device) in the network design model. A collapsed core design reduces cost, while maintaining most of the benefits of the network design model for small networks that do not grow significantly larger over time.

collision domain. A network segment where data frames can collide with one another when being sent on a shared medium such as Ethernet. Hosts in a collision domain arbitrate among themselves using an access control mechanism.

command-line interface (CLI). Environment for entering commands to configure and monitor routing and switching software and hardware.

committed information rate (CIR). The average rate at which packets are admitted to the network. Each packet is counted as it enters the network. Packets that do not exceed the CIR are marked green, which corresponds to low loss priority. Packets that exceed the CIR but are below the peak information rate (PIR) are marked yellow, which corresponds to medium loss priority.

common and internal spanning tree (CIST). A single topology connecting all Spanning Tree Protocol (STP), Rapid Spanning Tree Protocol (RSTP), Multiple Spanning Tree Protocol (MSTP) switches into one active topology. In other words, an entire spanning tree fabric.

common spanning tree (CST). The topology connecting all Spanning Tree Protocol (STP)/Rapid Spanning Tree Protocol (RSTP) *switches* and multiple spanning-tree (MST) region *instances*. An MST region appears as a single switch to spanning tree configurations outside the region.

community. In Border Gateway Protocol (BGP), a logical group of prefixes or destinations that share a common attribute; used to simplify a routing policy. Community members can be on different networks and in different autonomous systems.

In Simple Network Management Protocol (SNMP), an authentication scheme that authorizes SNMP clients based on the source IP address of incoming SNMP packets, defines which Management Information Base (MIB) objects are available, and specifies the operations (read-only or read-write) allowed on those objects.

congestion. The state in which the network load exceeds the available resources such as link capacity or memory buffers.

connection-oriented. A packet switching technology where a virtual circuit between sending and receiving devices makes it seem like the devices are connected by a switched circuit with a fixed bandwidth without regard to their physical addresses. In a connection-oriented service, packets always reach their destination in the same order as they were sent. Transmission Control Protocol (TCP) is a connection-oriented transport service. See also connectionless.

Connection-oriented protocols can be used to send information that requires a constant delay and bandwidth such as voice and video.

connectionless. A packet switching technology where the source and destination addresses are included in each packet so that a direct connection or an established session between sender and receiver is not required for communications. In a connectionless service, each packet is handled independently of all others, and packets might not reach their destination in the same order in which they were sent. User Datagram Protocol (UDP) is a connectionless transport service. See also connection-oriented.

Connectivity Fault Management (CFM). An Operation, Administration, and Maintenance (OAM) protocol that can manage Ethernet services and detect, verify, and isolate connectivity failures in VLANs. CFM enables service providers to configure:

- Maintenance association End Point (MEP) on a per-port, per-VLAN, or per-domain basis
- Maintenance domain Intermediate Point (MIP) on a per-port and per-level basis

CFM can operate over a LAN segment, customer VLAN (C-VLAN), service VLAN (S-VLAN), backbone VLAN (B-VLAN), or backbone identified by an I-SID (Service Instance Identifier). Defined by IEEE 802.1ag and 802.1ah.

Constrained Shortest Path First (CSPF). An extension of shortest path first (SPF). The path computed using CSPF is the shortest path that fulfills a set of constraints. After running the shortest path algorithm, the paths are pruned, removing those links that violate a given set of constraints.

See also Resource Reservation Protocol—Traffic Engineering (RSVP-TE).

Content Addressable Memory (CAM). An integrated circuit in a device that stores a table used to make frame forwarding and classification decisions. CAM can perform a massively parallel search of entries in the table much faster than a serial search than in conventional Random Access Memory (RAM).

There are two types of CAM:

- Binary CAM: A binary lookup that returns either a 1 or 0. A MAC address in an Ethernet frame comes into a switch, the switch looks in its MAC address table and either finds that MAC address or does not (1 or 0).
- Ternary CAM (TCAM): A binary lookup that returns either a 1 or 0 but also has a “do not care” bit. TCAM can have multiple matches and can determine a best match. This is necessary because Classless Interdomain Routing (CIDR) lookups need a longest prefix match. For example, 192.168.1.7/32 matches both 192.168.1.0/24 and 192.168.1.0/25. The closest match to 192.168.1.7/32 is 192.168.1.0/25 which would be chosen.

Continuity Check Message (CCM). A multicast Connectivity Fault Management (CFM) protocol data unit (PDU) transmitted periodically by a Maintenance association End Point (MEP) in ensure continuity over the Maintenance Association (MA) to which the transmitting MEP belongs.

control plane. The part of switch or router architecture that makes decisions about where traffic is sent. Control plane processing is the “signalling” of the network. Anything that is needed to get routing and switching working on a device is considered part of the control plane. The control plane serves the data plane.

The control plane functions include the manual system configuration and management operations performed by a network administrator. The control plane functions also include dynamic routing protocols such as Routing Information Protocol (RIP), Open Shortest Path First (OSPF), or Border Gateway Protocol (BGP) that exchange topology information with other routers and construct a Routing Information Base (RIB).

The control plane functions are not performed on each arriving individual packet, so they do not have a strict speed constraint and are not time-critical.

Control plane packets are sent to or are locally originated by the device itself.

convergence. The synchronization process that a network must go through immediately after a topology change. Convergence time is the time required to update all the devices on the network with the routing information changes. See also routing table.

core layer. In the network design model, the layer that provides a transit function to access the internal network and external networks. The core layer moves packets between distribution layer devices. The core layer also links to the devices at the enterprise edge to support Internet, virtual private networks (VPN), extranet, and WAN access.

The core layer uses Layer 3 (L3) routing protocols that scale well and converge quickly such as Open Shortest Path First (OSPF).

The core serves as the backbone for the network and is critical for connecting distribution layer devices, so it is important for the core to be fast with low-latency, reliable, and scalable.

Also called backbone or trunk.

count-to-infinity. A distance-vector routing problem where if A tells B that it has a path somewhere, there is no way for B to know if the path has B as a part of it.

The count-to-infinity problem is caused by a link failure that partitions the network into two or more segments. When the network is partitioned, devices in one part of the segment cannot reach devices in the other part of the segment. The distance-vector algorithm adjusts the distance value slowly upwards toward infinity.

The count-to-infinity problem can be solved through split horizon methods.

cryptography. Rendering information unintelligible and restoring encrypted information to an intelligible form.

customer edge (CE). A device that provides an interface between a Local Area Network (LAN) and an enterprise or service provider core network. Outbound packets from the LAN are forwarded from the CE to a provider edge (PE) device, and inbound packets are forwarded from the PE to the CE.

customer VLAN (C-VLAN). In a Provider Bridging (PB) frame, a field that identifies the customer VLAN. See also service VLAN (S-VLAN). Also called C-TAG.

D

daemon. A background program that runs unattended and is usually invisible to users and that provides important system services. Pronounced “dee-mon” or “day-mon”.

Data Center Bridging (DCB). A collection of extensions for Ethernet that allows LANs and Storage Area Networks (SANs) to use a single unified fabric in a data center. DCB can carry Fibre Channel, TCP/IP, and inter-process communication traffic over a single, converged Ethernet network. DCB features include:

- Priority-based Flow Control (PFC)
- Enhanced Transmission Selection (ETS)
- Quantized Congestion Notification (QCN)
- Data Center Bridging Capability Exchange (DCBX)

Data Center Bridging Capability Exchange (DCBX). Defined in IEEE 802.1Qaz, a protocol that uses Link Layer Discovery Protocol (LLDP) to convey configuration of Data Center Bridging (DCB) features between neighbors.

data communications equipment (DCE). The interface between data terminal equipment (DTE) and a network.

Data Encryption Standard (DES). A method of data encryption using a private (secret) key. There are 72 quadrillion or more possible encryption keys that can be used. For each given message, the key is chosen at random from among these. Both the sender and the receiver must know and use the same private key.

In triple DES (3DES), a symmetric-key block cipher applies the DES cipher algorithm three times to each data block.

data link layer. See Layer 2 (L2).

data plane. The part of switch or router architecture that forwards frames and packets arriving on an interface. Routers and switches use what the control plane has built to process incoming frames and packets. The data plane forwards traffic to the next hop along the path to the destination according to the control plane logic. Data plane frames or packets go *through* the device.

Also called forwarding plane.

data terminal equipment (DTE). Any device such as a host, router, or switch connected to a network. A DTE connects to a network through data communications equipment (DCE).

default gateway. A router that connects hosts on a network segment to the Internet.

default route. A route used to forward Internet Protocol (IP) packets when a more specific route is not present in the Routing Information Base (RIB). Often represented as 0.0.0.0/0, the default route is sometimes called the “route of last resort”.

Differentiated Services (DiffServ). A mechanism to classify and manage network traffic and provide Quality of Service (QoS) guarantees for service providers. DiffServ extends the Resource Reservation Protocol—Traffic Engineering (RSVP-TE). DiffServ enables traffic to be prioritized by class, so that certain kinds of traffic, for example voice traffic, can take precedence over other types of traffic.

DiffServ redefines bits in the type of service (ToS) field of an IP packet header. DiffServ uses the Differentiated Services Code Point (DSCP) field for the QoS priority and supports 64 levels of classification.

Defined by RFC 2474; Multi-Protocol Label Switching (MPLS) support is defined in RFCs 3270 and 4124.

Differentiated Services Code Point (DSCP). A six-bit field in an IP header that enables service providers to allocate resources on a per-packet basis to meet customer requirements. See also Differentiated Services (DiffServ).

Diffie–Hellman. A method of securely exchanging cryptographic keys that allows two parties with no prior knowledge of each other to jointly establish a shared secret key over an insecure channel. This key can then be used to encrypt subsequent communications using a symmetric key cipher.

Digital Signature Algorithm (DSA). An asymmetric cryptographic algorithm that produces a digital signature in the form of a pair of large numbers. The signature is computed using rules and parameters such that the identity of the signer and the integrity of the signed data can be verified.

Dijkstra algorithm. An algorithm used by Intermediate System to Intermediate System (IS-IS) and Open Shortest Path First (OSPF) to make routing decisions based on link state. Also called shortest path first (SPF). Contrast with Bellman-Ford algorithm.

distance-vector routing. A family of routing algorithms that calculate the best route to use to send data based on information from adjacent (directly connected) routers on the network.

“Distance-vector” means that routes are advertised with two characteristics:

- Distance: How far it is to the destination based on a metric such as the number of hops, cost, bandwidth, or delay.
- Vector: The direction (exit interface) of the next hop router to reach the destination.

Each router sends its neighbors a list of networks it can reach and the distance to that network. For each network path, the receiving router picks the neighbor advertising the lowest metric, then adds this entry into its Routing Information Base (RIB). These best paths are advertised to each adjacent router.

Routing information is broadcast periodically rather than only when a change occurs, which makes the method compute- and bandwidth-intensive. For this reason, a distance-vector algorithm is best used in relatively small networks with few interrouter connections.

The Bellman-Ford algorithm is often used to determine the best path, which is used by the Routing Information Protocol (RIP).

Distance-vector routing can be prone to routing loops which are avoided through split horizon techniques.

Contrast with link-state routing and shortest-path routing.

distribution layer. In the network design model, the layer that aggregates the data received from the access layer and sends it to the core layer or to other segments of the local network. Routers or multilayer switches in the distribution layer performs many functions including:

- Routing between subnetworks and Virtual Local Area Network (VLAN) instances in the access layer
- Managing access control, routing, filtering, and QoS policies
- Managing firewalls and network address translation (NAT)
- Managing queues and prioritizing traffic
- Summarizing routes before advertising them to the core
- Isolating the core from access layer failures or disruptions

The distribution layer uses Layer 3 (L3) routing to connect to the core layer and Layer 2 (L2) switching to connect to the access layer.

Also called the aggregation layer or concentration layer.

domain. A representation of all or a subset of a network used for addressing and administrative purposes. Also refers to a collection of routers that use a common Interior Gateway Protocol (IGP). See also area and autonomous system (AS).

domain name. A meaningful and easy-to-remember name for an IP address. A domain name is a sequence of names (labels) separated by periods such as “example.com”.

Domain Name Service (DNS). A service that translates a domain name into a numeric IP address needed to locate devices. The DNS database is hierarchical. When a client such as a Web browser gives a request that specifies a host name, the DNS resolver on the client first contacts a DNS server to determine the server's IP address. If the DNS server does not contain the needed mapping, it forwards the request to a different DNS server at the next higher level in the hierarchy. After potentially several forwarding and delegation exchanges within the DNS hierarchy, the IP address for the given host eventually arrives at the client. Defined in RFCs 1034 and 1035.

dotted decimal. A method of representing an IPv4 address as four decimal numbers separated by dots, or periods; for example, 194.65.87.3. See also IP address.

double colon. A notation used to represent a consecutive block of zeroes in the middle of an IPv6 address. For example, given this address:

FE80:0000:0000:0000:0202:B3FF:FE1E:8329

With double colon notation, the address shown above becomes:

FE80::0202:B3FF:FE1E:8329

You can only use the double colon notation once in an address.

double tagged. See Provider Bridging (PB).

dynamic address. An address assigned to a device on a network with no regard to matching a specific address to that device. When a client device (such as a laptop) is given a dynamic address, it simply receives one from a pool of available addresses. It might or might not be allocated the same IP address as on previous connections. See also Dynamic Host Configuration Protocol (DHCP).

Dynamic Host Configuration Protocol (DHCP). A protocol where a client can obtain an IP address and other information such as default gateway, subnet mask, and Domain Name Service (DNS) servers, for the client to use to connect to a network. Defined in RFCs 2131 and 3315. See also Transmission Control Protocol/Internet Protocol (TCP/IP).

A DHCP server “leases” an IP address for a predetermined period of time, and reclaims the address for reassignment at the expiration of that period. DHCP greatly simplifies the administration of large networks, and networks in which nodes such as laptops, tablets, and smart phones frequently join and leave.

dynamic routing. A technique used by routing protocols where devices send and receive messages about the network topology to and from other devices and update a local Routing Information Base (RIB) used to locate the best available path to a destination.

There are different forms of dynamic routing: distance-vector routing, link-state routing, and path-vector routing. Several protocols use dynamic routing such as Border Gateway Protocol (BGP), Intermediate System to Intermediate System (IS-IS), Open Shortest Path First (OSPF), and Routing Information Protocol (RIP).

Also called adaptive routing. Contrast with static routing.

E

east/west. The flow of traffic traversing a data center or cloud horizontally between servers. Contrast with north/south.

Edge Virtual Bridging (EVB). A mechanism that enables a virtual switch to send all traffic to an adjacent physical switch. This moves the forwarding decisions and network operations from the host CPU to the switch. EVB leverages the advanced management capabilities in access or aggregation layer switches. Defined by IEEE 802.1Qbg.

egress. Outbound or outgoing, referring to a protocol data unit (PDU) exiting a device. See also ingress.

encapsulation. The technique used by layered protocols in which a layer adds its own header information to the protocol data unit (PDU) from the layer above. As an example, in the Open Systems Interconnection (OSI) Reference Model, a PDU can contain a header for Layer 1 (L1), followed by a header for Layer 2 (L2), followed by a header for the Layer 3 (L3), followed by a header for the transport layer (Transmission Control Protocol (TCP), followed by data for the higher layers.

encryption. The process of encoding information in an attempt to make it secure from unauthorized access, particularly during transmission. The reverse of this process is known as decryption. Two main encryption schemes are in common use:

- Private (symmetrical) key: Using a private encryption key known to both the sender and the receiver of the information.
- Public (asymmetrical) key: Using a public key to encrypt and a private key to decrypt.

See also Data Encryption Standard (DES).

end-of-row switch. A chassis-based switch in a rack or cabinet at either end of the server row in a data center that connects to hundreds of servers in that row. Each cabinet in the row has cabling connecting 48 (or more) servers to the end-of-row switch. An end-of-row switch typically has redundant supervisor engines, power supplies, and overall better high availability characteristics than a Top-of-Rack (ToR) switch.

An end-of-row switch extends Layer 1 (L1) cabling topology from the switch to each rack, resulting in a smaller Layer 2 (L2) footprint and fewer Spanning Tree Protocol (STP) nodes in the topology.

Enhanced Transmission Selection (ETS). A protocol for assigning bandwidth to frame priorities. Defined in IEEE 802.1Qaz.

equal-cost multipath (ECMP). A forwarding mechanism for routing traffic along multiple paths of equal cost that ensures load balancing. The link-state routing protocols that use a cost-based metric such as Intermediate System to Intermediate System (IS-IS) and Open Shortest Path First (OSPF) explicitly allow ECMP routing.

Encapsulating Security Payload (ESP). An Internet Protocol Security (IPsec) protocol that ensures confidentiality by encrypting IP packets. An encryption algorithm combines the data in a packet with a key to transform the packet into an encrypted form. At the destination, the packet is decrypted it using the same algorithm. ESP also

ensures the integrity of a packet using a hash message authentication code (HMAC). ESP also supports an authentication scheme like that used in Authentication Header (AH), or can be used in conjunction with AH.

Ethernet. A specification for a LAN technology at Layer 1 (L1) and Layer 2 (L2) of the Open Systems Interconnection (OSI) Reference Model based on packetized transmissions between physical ports over a variety of electrical and optical media. Ethernet can transport several upper-layer protocols, the most popular of which is Transmission Control Protocol/Internet Protocol (TCP/IP). Ethernet standards are maintained by the IEEE 802.3 committee.

Ethernet uses a bus topology and CSMA/CD (Carrier Sense Multiple Access/Collision Detection) to resolve contention when two devices try to access the network at exactly the same time. Transmission speeds range from 10 Mbps, to Fast Ethernet at 100 Mbps, to Gigabit Ethernet at 1000 Mbps.

Ethernet Linear Protection Switching (ELPS). A type of Automatic Protection Switching (APS) that specifies these techniques:

- Linear 1+1 (One-plus-One) operates with either uni-directional or bi-directional switching; normal traffic is copied and fed to both working and protection transport entities
- Linear 1:1 (One-to-One) operates with bi-directional switching; normal traffic is transported either on the working transport entity or on the protection transport entity, using a selector bridge at the source

Defined by ITU-T G.8032.

Ethernet Local Management Interface (E-LMI). An Operation, Administration, and Maintenance (OAM) protocol for communications between two User-to-Network Interface (UNI) instances. E-LMI provides both UNI and Ethernet Virtual Connection (EVC) status information to customer edge devices. This information enables automatic configuration of customer edge operation based on the configuration. Defined by Metro Ethernet Forum (MEF) 16.

Ethernet Ring Protection Switching (ERPS). A type of Automatic Protection Switching (APS) that protects traffic in a ring topology by ensuring that no loops are within the ring. Loops are prevented by blocking traffic on either a predetermined link or a failed link. ERPS integrates Operation, Administration, and Maintenance (OAM) functions with a simple APS protocol. An Ethernet ring uses normal learning, forwarding, filtering, and flooding mechanisms and a forwarding database (FDB). Defined by ITU-T G.8032.

Ethernet to the First Mile (EFM). A set of extensions to the 802.3 MAC and MAC sub layer. EFM describes technologies and the physical layer specifications for subscriber access, including remote failure detection, remote loop back, and link monitoring. Defined by IEEE 802.3ah.

Ethernet Virtual Connection (EVC). An association of two or more instances of a User-to-Network Interface (UNI). There are three types of EVC:

- In a point-to-point EVC, exactly two UNIs are associated with one another.
- In a multipoint EVC, two or more UNIs are associated with one another.
- In a rooted-multipoint EVC, one or more of the UNIs must be designated as root and each of the other UNIs must be designated as a leaf. If root, the UNI can send service frames to all other points in the EVC; if leaf, the UNI can send and receive service frames to and from root only.

Explicit Route Object (ERO). An extension to Resource Reservation Protocol (RSVP) that allows a path message to traverse an explicit sequence of routers that is independent of conventional shortest-path IP routing.

Exterior Gateway Protocol (EGP). An interdomain protocol such as Border Gateway Protocol (BGP) used to exchange network reachability information between autonomous system (AS) instances. Contrast with Interior Gateway Protocol (IGP).

F

FEC-to-NHLFE (FTN) map. In Multi-Protocol Label Switching (MPLS), a mapping from the forwarding equivalence class (FEC) of incoming packets to the corresponding Next Hop Label Forwarding Entry (NHLFE).

filtering. The process of determining whether to forward a frame or packet through a port. The simplest form of filtering is to not forward frames out the same port on which they were received. A network administrator can configure filtering manually or a device can be "self-learning" and record the source addresses of devices on each segment of a network in a filtering database.

Filtering behavior is sometimes referred to as "drop, flood, or forward":

- If the switch determines that the destination MAC is on the same port, it does not forward the frame, dropping it.
- If the switch determines that the destination MAC is on a different port, it forwards the frame on that port.
- If the switch does not know where to send the frame (or if it is multicast or broadcast), the frame is flooded out all ports (except the port it was received on).

filtering database. A data structure in a switch that maps addresses to ports, addresses to VLANs, and/or ports to VLANs. A switch learns the location of hosts by recording the source MAC address-port number association for each frame received at an incoming port. All future transmissions destined to a MAC address in the filtering database are only directed to the port associated with that MAC address unless the transmission originated on that port.

A switch can also be configured and act as several independent switches by creating VLAN associations to switch ports.

flapping. Condition of network instability when a route is announced and then withdrawn repeatedly, usually as the result of an intermittently failing link. Also called route flapping.

flooding. Forwarding a frame onto all ports except the port upon which it arrived. In Open Shortest Path First (OSPF), distributing and synchronizing the link-state database (LSDB) between routers.

flow control. Any mechanism that prevents a source from sending faster than the destination is capable of receiving.

Forward Error Correction (FEC). A system of error control that allows the receiver to correct some errors without having to request a re-transmission of data.

forwarding. Finding the output port to which a frame needs to go, and relaying the frame to that port.

forwarding equivalence class (FEC). A set of packets with similar characteristics that are forwarded in the same manner, on the same path, with the same forwarding treatment, and using the same Multi-Protocol Label Switching (MPLS) label. FECs are defined by the Label Distribution Protocol (LDP). FECs are also represented in other label distribution protocols.

Forwarding Information Base (FIB). A data structure used to find the interface to which to forward a packet. The FIB contains the minimum amount of information required to make a forwarding decision for a particular packet, such as destination prefix and nexthop. The FIB is an abbreviated form of the information in the Routing Information Base (RIB).

Also called forwarding table.

frame. A protocol data unit (PDU) at Layer 2 (L2) with addressing and protocol control information. A frame contains a header field and a trailer field that "frame" the user data. (Some control frames contain no data.)

See also packet.

G

GARP Multicast Registration Protocol (GMRP). A Generic Attribute Registration Protocol (GARP) application that allows switches to exchange multicast group information with other GMRP switches, prune unnecessary broadcast traffic, and dynamically create and manage multicast groups. See also Multiple MAC Registration Protocol (MMRP).

GARP VLAN Registration Protocol (GVRP). A Generic Attribute Registration Protocol (GARP) application that provides VLAN registration services. A switch can exchange VLAN configuration information with other GVRP switches, prune unnecessary broadcast and unknown unicast traffic, and dynamically create and manage VLANs. Defined by 802.1Q. See also Multiple VLAN Registration Protocol (MVRP).

gateway. A device that understands and converts between two different networking models. Since Transmission Control Protocol/Internet Protocol (TCP/IP) has become the dominant model, gateways are not used much at this time.

See also default gateway.

Generic Attribute Registration Protocol (GARP). A generic framework for devices to register attributes, such as VLAN identifiers and multicast group membership. See also Multiple Registration Protocol (MRP).

generic routing encapsulation (GRE). A tunneling protocol that encapsulates Layer 3 (L3) packets inside IP packets. GRE provides a virtual point-to-point link over an IP network. GRE is completely insecure, but provides a fast and simple way to access a remote network.

graceful restart. A process that allows a router whose control plane is restarting to continue forwarding traffic while recovering its state from neighboring routers. Without graceful restart, a control plane restart disrupts services provided by the router. Also called nonstop forwarding.

gratuitous ARP. Broadcast request for a router's own IP address to check whether that address is being used by another node. Used to detect IP address duplication.

H

hash message authentication code (HMAC). A method of calculating a message authentication code (MAC) using a cryptographic hash function in combination with a secret cryptographic key. As with any MAC, it can be used to simultaneously verify both the data integrity and the authenticity of a message. Any cryptographic hash function, such as MD5 or SHA-2, can be used to calculate an HMAC.

header. The portion of a protocol data unit (PDU) that contains control information for the message such as destination address, source address, input sequence number, the type of message, and priority level.

hello packet. A multicast packet that is used by protocols for neighbor discovery and recovery. Hello packets also indicate that a client is still operating and network-ready.

high availability. The ability of a system or component to limit or avoid network disruption when a component fails. High availability provides both hardware and software methods to minimize downtime and improve the performance of a network.

hold down. A state that a route is placed into so that devices will neither advertise the route nor accept advertisements about the route for a specific length of time (the hold down period). A hold down is used to flush bad information about a route from all devices in a network. A route is placed into hold down when a link in that route fails.

hop. A single link between two computer systems that a protocol data unit (PDU) must cross on its way to its destination. See also hop count.

hop count. The number of links that must be crossed to get from a source to a destination. A protocol data unit (PDU) might pass over many hops to reach its destination. If it must pass between five computers, it is said to have taken four hops to reach its destination. Hop count is often used as a metric for evaluating a route in distance-vector routing. Routing Information Protocol (RIP) uses hop count as its sole metric.

host. A computer connected to a network that is assigned a Layer 3 (L3) address and that provides an access point to that network. Similar to a node, except that host usually implies a computer system, whereas node generally applies to any networked device such as a router or switch.

hypervisor. A thin operating system designed solely to provide virtualization. A hypervisor drives physical hardware, executes virtual machine (VM) instances, and dynamically shares the underlying hardware with the associated virtual hardware. A hypervisor does not serve as a general-purpose operating system, but instead provides the platform on which VMs can run.

I

I-SID (Service Instance Identifier). A field in an I-TAG that defines the service instance to which the Provider Backbone Bridging (PBB) frame is mapped.

I-TAG. Field in the Provider Backbone Bridging (PBB) header that carries the I-SID (Service Instance Identifier) associated with the frame.

Incoming Label Map (ILM). In Multi-Protocol Label Switching (MPLS), a mapping from incoming labels to corresponding Next Hop Label Forwarding Entry (NHLFE).

ingress. Inbound or incoming, referring to a protocol data unit (PDU) entering a device. See also egress.

Institute of Electrical and Electronics Engineers (IEEE). A coordinating body for computing and communications standards. The IEEE mainly covers Layer 1 (L1) and Layer 2 (L2) of the Open Systems Interconnection (OSI) Reference Model. (Pronounced “eye-triple-ee”.) See http://www.ieee.org.

interface. The point at which a connection is made between two devices. An interface describes the logical and physical connections and usually means the same thing as the term port.

Interior Gateway Protocol (IGP). An intradomain protocol used to exchange network reachability and routing information among devices within an autonomous system (AS), such as Intermediate System to Intermediate System (IS-IS), Open Shortest Path First (OSPF), or Routing Information Protocol (RIP). Contrast with Exterior Gateway Protocol (EGP).

Intermediate System to Intermediate System (IS-IS). An Interior Gateway Protocol (IGP) that floods link state information throughout a network of routers. Each IS-IS router independently builds a database of the network's topology, aggregating the flooded network information. A Routing Information Base (RIB) is calculated from the database by constructing a shortest path tree (SPT).

Like Open Shortest Path First (OSPF), IS-IS uses the Dijkstra algorithm to find the best path through a network. Packets are then forwarded, based on the computed ideal path, through the network to the destination.

Defined by International Organization for Standardization (ISO) 10589.

internal spanning tree (IST). A special type of multiple spanning-tree instance (MSTI) that runs in an multiple spanning-tree (MST) region. An IST connects all the switches in the MST region and appears as a subtree in the common and internal spanning tree (CIST) that encompasses the entire switched domain.

An IST is identified by the number zero (0) and exists on all ports; you cannot delete the IST. By default, all VLANs are assigned to the IST. The IST is the only spanning tree instance that sends and receives bridge protocol data unit (BPDU) messages.

Any other spanning tree instance within an MST region is called a multiple spanning-tree instance (MSTI).

International Organization for Standardization (ISO). An international standards body that establishes global standards for communications and information exchange. Voting members are designated standards bodies of participating nations; American National Standards Institute (ANSI) is the U.S. member of the ISO. The Open Systems Interconnection (OSI) Reference Model is one of the ISO's most widely accepted recommendations.

Sometimes mistakenly referred to as the "International Standards Organization". Because "International Organization for Standardization" has different acronyms in different languages (IOS in English, OIN in French for *Organisation internationale de normalisation*), the founders gave it the short form ISO. ISO is derived from the Greek *isos*, meaning "equal".

For more, see http://www.iso.org/iso/home.html.

International Telecommunication Union (ITU). An international organization that develops standards for telecommunications. Formerly known as the CCITT. See http://www.itu.int.

Internet. The world's largest computer network, serving universities, commercial interests, government agencies, and private individuals. The Internet uses Transmission Control Protocol/Internet Protocol (TCP/IP) protocols, and Internet computers and devices run many different operating systems.

No government agency, single person, or corporate entity controls the Internet. All decisions on methods and standards are made by standards groups based on input from users.

See also Internet Engineering Task Force (IETF); Request for Comments (RFC).

Internet Control Message Protocol (ICMP). An Internet Protocol (IP) that provides management and control functions. Routers send ICMP messages to respond to undeliverable datagrams by placing an ICMP message in an IP datagram and then sending the datagram back to the original source. ICMP is also used by the ping (packet internet groper) command and enables a host to discover addresses of operating routers on the subnet. Defined in RFC 792.

IPv6 makes greater use of ICMP (ICMPv6 defined in RFC 4443) than IPv4, including neighbor solicitation, neighbor advertisement, router solicitation, router advertisement, and redirect.

Internet Engineering Task Force (IETF). An international community of network designers, operators, vendors, and researchers that develops Request for Comments (RFC) documents that define protocols and specifications for the Internet. The IETF mainly covers Layer 2 (L2) and Layer 3 (L3) of the Open Systems Interconnection (OSI) Reference Model. See http://www.ietf.org.

Internet Group Management Protocol (IGMP). An IPv4 protocol that allows hosts to add or remove themselves from a multicast group. Defined by RFC 3376.

IGMP enables receivers to register that they want to receive a particular multicast transmission, but does not route multicast traffic from the source to receivers. That task is left to a multicast routing protocol, such as Protocol Independent Multicast (PIM).

See also Multicast Listener Discovery (MLD), multicast group, (S,G).

Internet Key Exchange (IKE or IKEv2). An Internet Protocol Security (IPsec) protocol used to set up a security association (SA) by negotiating keys in secret. IKE builds upon Internet Security Association and Key Management Protocol (ISAKMP) using X.509 certificates for authentication and a Diffie–Hellman key exchange to set up a shared session secret from which cryptographic keys are derived. In addition, a security policy for every peer which will connect must be manually maintained.

The IKE protocol runs in two phases. The first phase establishes a ISAKMP SA which is used in the second phase to negotiate and set up the IPsec SAs.

Internet Protocol (IP). A Layer 3 (L3) protocol that provides connectionless delivery of data across heterogeneous physical networks. IP provides features for addressing, type-of-service, fragmentation and reassembly, and security. Defined by RFCs 791 and 1349.

Each computer (known as a host) on the Internet has at least one IP address that uniquely identifies it from all other computers on the Internet.

IP is best effort and provides no guarantees of reliability, so if packets are lost in transit, accidentally duplicated, arrive in the wrong order, or arrive corrupted, no effort is made to address the problem on the IP level—that is left to protocols a layer above, such as Transmission Control Protocol (TCP).

Internet Protocol Security (IPsec). A protocol suite for securing IP communications by authenticating and encrypting packets during a communication session. Authentication Header (AH) and Encapsulating Security Payload (ESP) are the main wire-level protocols used by IPsec. Before either AH or ESP can be used, however, the two devices must share a public key through Internet Key Exchange (IKE or IKEv2).

RFC 2401 specifies the base architecture for IPsec compliant systems. RFCs 2402, 2406, and 2407 provide more details about IPsec.

Internet Security Association and Key Management Protocol (ISAKMP). A framework for authentication and key exchange with actual authenticated keying material provided either by manual configuration with pre-shared keys or Internet Key Exchange (IKE or IKEv2). See also Internet Protocol Security (IPsec).

IP address. A unique number that identifies a device on an Internet Protocol (IP) network. IP addresses have two formats:

- An IPv4 address is 32 bits and is usually written in dotted decimal notation as four decimal numbers separated by periods. For example, 192.168.50.4 is an IPv4 address.
- An IPv6 address is 128 bits and is written in a hexadecimal notation of eight 16-bit parts separated by colons. For example, FE80:0000:0000:0000:0202:B3FF:FE1E:8329 is an IPv6 address. In the double colon address format, consecutive colons (“::”) represent successive 16-bit blocks that contain zeros: FE80::0202:B3FF:FE1E:8329. While a much larger address space is a feature, IPv6 also has other features such as multicast support, jumbograms (packets up to 4 GB in size), and stateless host auto-configuration.

Table 13-102 compares the IPv4 and IPv6 address formats.

Table 13-102: IPv6 and IPv4 Address Formats

Feature	IPv6	IPv4
Address space	128-bits = 3.4 x 1038 (340 unidecillion)	32-bits = 4.3 x 109 (4.2 billion)
Field separator	colon (:)	period (.)

Table 13-102: IPv6 and IPv4 Address Formats

Feature	IPv6	IPv4
Notation	hexadecimal	decimal
Example	db8:0:0:1	0.23.2.3

Each IP address contains a network part, an optional subnetwork part, and a host part. The network and subnetwork parts together are used for routing, while the host part is used to address an individual host within the network or subnetwork. A subnet mask is used to extract network and subnetwork parts from the IP address. Classless Interdomain Routing (CIDR) provides a way to represent IP addresses and subnet masks.

IP addresses are difficult to remember, so people tend to refer to computers by their domain names instead.

IPv6 Provider Edge (6PE). A protocol that enables IPv6 domains to communicate with each other over an Multi-Protocol Label Switching (MPLS) IPv4 core network. V6PE routers are “dual stack” and run both IPv4 and IPv6. Multiprotocol Border Gateway Protocol (BGP) (MP-BGP) in the IPv4 network is used to exchange IPv6 reachability information along with a label for each IPv6 prefix announced. Defined in RFC 4798.

Also called V6PE.

K

keepalive message. A message sent between devices when no data traffic has been detected for a given period of time. This communication verifies that the virtual and physical connection between the devices is still active.

kernel. The part of an operating system that performs basic functions such as allocating hardware resources.

KVM (Kernel-based Virtual Machine). A virtualization infrastructure for the Linux kernel that turns it into a hypervisor. KVM requires a processor with hardware virtualization technology extensions. By itself, KVM does not perform any emulation. Instead, KVM exposes an interface with which a user space host can then set up guest virtual machine (VM) instances.On Linux, QEMU (Quick EMUlator) is one such user space host.

L

Label Distribution Protocol (LDP). A protocol for distributing labels in non-traffic-engineered applications. LDP allows routers to create label-switched path (LSP) instances through a network by mapping network layer routing information directly to data-link layer switched paths.

A label is a short fixed-length, locally-significant identifier that identifies a forwarding equivalence class (FEC).

LDP works with other routing protocols such as Routing Information Protocol (RIP), Open Shortest Path First (OSPF), and Border Gateway Protocol (BGP) to create LSPs.

See also Resource Reservation Protocol—Traffic Engineering (RSVP-TE).

label edge router (LER). A router that operates at the edge of an Multi-Protocol Label Switching (MPLS) network and acts as the entry and exit points for the network.

When forwarding IP packets into an MPLS domain, an LER makes the initial path selection, add the appropriate labels to the packet, and forwards the labelled packets into the MPLS domain. Likewise, upon receiving a labelled packet which is destined to exit the MPLS domain, the LER strips off the label and forwards the resulting IP packet using

normal IP forwarding rules. (Under penultimate hop popping (PHP), the popping function might be performed by an label switch router (LSR) directly connected to the LER.)

Also called an edge LSR.

label switch router (LSR). A Multi-Protocol Label Switching (MPLS) router located in the middle of a MPLS network. When an LSR receives a packet, it uses the label included in the packet header to determine the next hop on the label-switched path (LSP) and find a corresponding label for the packet from a lookup table. The old label is then removed from the header and replaced with the new label before the packet is forwarded.

Also called transit router.

label-switched path (LSP). A sequence of routers that cooperatively perform Multi-Protocol Label Switching (MPLS) operations for a packet stream. An LSP is a unidirectional, point-to-point, half-duplex connection carrying information downstream from the ingress (first) router to the egress (last) router. The ingress and egress routers cannot be the same device.

latency. Delay in the transmission through a network from source to destination. See also line rate, wire speed.

Layer 1 (L1). The physical layer in the Open Systems Interconnection (OSI) Reference Model that conveys the bit stream through electrical impulse, light waves, or radio signals through the network. L1 represents the basic network hardware and specifies the type of medium used for transmission and the network topology.

Layer 2 (L2). The data link layer in the Open Systems Interconnection (OSI) Reference Model that provides reliable transit of data across a physical link between two directly connected devices. L2 refers to physical addressing, network topology, line discipline, error notification, sequenced delivery of frames, and flow control.

L2 transfers data between network entities by splitting data into frames to send on Layer 1 (L1) and receiving acknowledgment frames. The data link layer performs error checking and retransmits frames not received correctly. In general, the data link layer controls the flow of information across the link, providing an error-free virtual channel to Layer 3 (L3).

The data-link layer has two sublayers:

- logical link control (LLC)
- Media Access Control (MAC)

Also called link layer.

Layer 3 (L3). The network layer in the Open Systems Interconnection (OSI) Reference Model that routes packets of data from source to destination across a network. L3 provides network-wide communication, including global addressing, lifetime control, fragmentation, and reassembly. Internet Protocol (IP) is an example.

Layer 4 (L4). The transport layer in the Open Systems Interconnection (OSI) Reference Model that provides logical communication between processes running on different hosts. L4 manages the end-to-end delivery of payload from a source to a destination within and between networks while maintaining the quality of service. Transmission Control Protocol (TCP) is an example.

Lightweight Directory Access Protocol (LDAP). A protocol used to locate organizations, individuals, and other resources in a network. Defined in RFC 4511. See also authentication, authorization, and accounting (AAA), Remote Authentication Dial In User Service (RADIUS), Terminal Access Controller Access Control System Plus (TACACS+).

line rate. Total number of physically transferred bits per second, including useful data and protocol overhead, over a communication link. For example, if the line rate of a link is 10 Gbps, the link transmits 10 gigabits of data every second over its physical interface. Contrast with throughput. See also latency, wire speed.

link. Communication path between two neighbor nodes.

link aggregation. A method for using multiple parallel links between a pair of devices as if they were a single higher-performance channel. The aggregated interface is viewed as a single link to each device. Spanning Tree Protocol (STP) also views it as one interface. Link aggregation can also be used to increase availability so that when there is a failure in one physical link, the remaining links stay up, and there is no disruption. Defined by IEEE 802.1AX.

Also called link aggregation group (LAG), LAG bundle, and EtherChannel. See also Link Aggregation Control Protocol (LACP), Multi-Chassis Link Aggregation (MC-LAG).

Link Aggregation Control Protocol (LACP). Mechanism for exchanging port and system information to create and maintain link aggregation groups.

link cost. An arbitrary number configured on an Open Shortest Path First (OSPF) interface which is used in shortest path first calculations.

Link Layer Discovery Protocol (LLDP). A mechanism for the devices on a network to advertise their identity, capabilities, and neighbors to each other. Defined by IEEE 802.1AB.

link state. Information about a link and link cost to neighboring routers.

link-state advertisement (LSA). An Open Shortest Path First (OSPF) protocol data unit (PDU) to share information on the operating state of a link, link cost, and other OSPF neighbor information. LSAs are used by the receiving routers to update their Routing Information Base (RIB)s.

link-state database (LSDB). The data structure on a router that contains all routing knowledge in a link-state network. An LSDB stores all link-state advertisement (LSA) instances produced by a link-state routing protocol such as Open Shortest Path First (OSPF) or Intermediate System to Intermediate System (IS-IS). Each router runs shortest path first (SPF) algorithm against this database to locate the best network path to each destination in the network.

link-state routing. A routing technique used by Open Shortest Path First (OSPF) and Intermediate System to Intermediate System (IS-IS) where each router shares information with other routers by flooding information about itself to every reachable router in the area. Link-state protocols use characteristics of the route such as speed and cost to determine the best path. Link-state information is transmitted only when something has changed in the network.

Every router constructs a map of the connectivity of the network, determining the interconnections between all routers. As a router receives an advertisement, it stores this information in a link-state database (LSDB). Each router then independently calculates the best next hop from it to every possible destination in the network using the shortest path first (SPF) algorithm to build a shortest path tree (SPT) with itself as the center of that tree. The shortest path to each reachable destination within the network is found by traversing the tree. The collection of best next hops forms the router's Routing Information Base (RIB).

Link-state algorithms create a consistent view of the network and are therefore not prone to routing loops, but they achieve this at the cost of more computing cycles and more traffic compared to distance-vector routing.

See also Dijkstra algorithm.

Linktrace Message (LTM). A Connectivity Fault Management (CFM) protocol data unit (PDU) initiated by a Maintenance association End Point (MEP) to trace a path to a target MAC address, forwarded from Maintenance domain Intermediate Point (MIP) to MIP, up to the point at which the LTM reaches its target MEP.

Linux. A Unix-like computer operating system assembled under the model of free and open source software development and distribution. The defining component of Linux is the kernel, the central part of the operating system that manages system services. Many people use the name “Linux” to refer to the complete operating system package which is called a Linux distribution which is made up of a collection of software based around the Linux kernel.

Linux has since been ported to more computer hardware platforms than any other operating system and is available for a wide variety of systems from small embedded systems up to supercomputers. In particular, networking devices such as switches and routers almost universally run some Linux distribution.

As an open operating system, Linux is developed collaboratively, meaning no one organization is solely responsible for its development or ongoing support. Companies participating in the Linux community share research and development costs with their partners and competitors.

Local Area Network (LAN). A group of computers and devices connected by a communications channel, capable of sharing resources among several users. LANs are based on a small physical area such as a building, floor, or department. LANs can connect to a wide area network (WAN). Ethernet is the most popular LAN technology.

logical link control (LLC). The higher sublayer of Layer 2 (L2) in the Open Systems Interconnection (OSI) Reference Model. The LLC sublayer provides the interface for Layer 3 (L3) and handles error control, flow control, framing, and MAC-sublayer addressing. The most prevalent LLC protocol is IEEE 802.2, which includes both connectionless and connection-oriented variants. See also Media Access Control (MAC).

loopback. A troubleshooting test in which a signal is transmitted from a source to a destination and then back to the source again so that the signal can be measured and evaluated.

M

MAC address. A permanent, unique serial number that uniquely identifies a network device among all other network devices in the world. MAC addresses are 12-digit numbers, 48 bits in length. MAC addresses are usually written as six groups of two hexadecimal digits, separated by hyphens (“-”) or colons (“:”):

MM:MM:MM:SS:SS:SS

MM-MM-MM-SS-SS-SS

Each pair of hexadecimal digits represents one byte of the 6-byte (48-bit) address.

An example of a MAC address is 68:A3:C4:3B:8D:24:

- The first three parts (68:A3:C4) identify the manufacturer (Liteon Technologies)
- The second three parts (3B:8D:24) is the serial number assigned by the manufacturer

At Layer 2 (L2), other devices use MAC addresses to locate specific ports in a network, and to create and update a Routing Information Base (RIB). A MAC address maps to an IP address through the Address Resolution Protocol (ARP).

Also called physical address, Ethernet address, or hardware address.

MAC-in-MAC. See Provider Backbone Bridging (PBB).

Maintenance Association (MA). In Connectivity Fault Management (CFM), a set of Maintenance association End Point (MEP) instances, each configured with the same MAID (Maintenance Association Identifier) and Maintenance Domain (MD) Level, established to verify the integrity of a single service instance.

Maintenance association End Point (MEP). A Connectivity Fault Management (CFM) entity at the edge of a Maintenance Domain (MD) that confines CFM messages within the domain via the MD level. MEPs periodically transmit and receive Continuity Check Message (CCM) instances from other MEPs within the domain. MEPs are either “Up” (toward the switch) or “Down” (toward the wire).

Maintenance Domain (MD). In Connectivity Fault Management (CFM), the network or the part of the network for which faults in connectivity can be managed.

Maintenance domain Intermediate Point (MIP). A Connectivity Fault Management (CFM) entity that catalogs and forwards information received from Maintenance association End Point (MEP) instances. MIPs are passive points that respond only to CFM Linktrace Message (LTM) and loopback messages.

Management Information Base (MIB). A specification of objects used by Simple Network Management Protocol (SNMP) to monitor or change network settings. MIBs provides a logical naming scheme for resources on a network. A MIB contains information about a device such as settings, usage statistics, performance data, or physical properties (such as temperature or fan speed). MIB objects are organized in a tree structure that includes public (standard) and private (proprietary) branches. Standard MIBs are defined by the IETF.

Maximum Transmission Unit (MTU). The maximum number of bytes in a packet or frame. For Ethernet, the default MTU is 1500 bytes (data payload), but each media has different sizes. The Ethernet MTU is defined in RFC 894.

Media Access Control (MAC). The lower sublayer of Layer 2 (L2) in the Open Systems Interconnection (OSI) Reference Model. The MAC sublayer provides addressing and channel access control mechanisms that make it possible for several network nodes to communicate within a multiple-access network that uses a shared medium such as Ethernet. The MAC sublayer is the interface between the logical link control (LLC) sublayer and Layer 1 (L1).

mesh. A physical or logical network topology in which devices have many redundant interconnections. A full mesh is when all devices in a network have a connection to all other devices, a partial mesh is when some devices have a connection to all other devices.

Metro Ethernet Forum (MEF). A defining body for Carrier Ethernet with many participating organizations including service providers, and network hardware and software manufacturers. The MEF's mission is to accelerate the worldwide adoption of carrier-class Ethernet networks and services. For more, see http://metroethernetforum.org/.

Multi-Chassis Link Aggregation (MC-LAG). A technique that extends the link aggregation concept. At either one or both ends of a link aggregation group, a single aggregation system is replaced by a *portal* that is a collection of one to three portal systems. Defined by IEEE 802.1AX.

Also called MLAG and Distributed Resilient Network Interconnect (DRNI).

Multi-Protocol Label Switching (MPLS). A method for forwarding packets through a network. MPLS operates between the traditional definitions of Layer 2 (L2) and Layer 3 (L3).

In a traditional IP network, each router performs an IP lookup to determine a next hop based on its routing table, and forwards the packet to that next hop. Every router in the path repeats this process, making its own independent routing decisions, until the final destination is reached.

In an MPLS network, the first device does a routing lookup, but instead of finding a next hop, it finds the final destination router and finds a pre-determined path from the source to the destination. The router applies a "label" based on this information. Other routers in the path use the label to route the traffic without needing to perform any additional IP lookups.

At each incoming (ingress) point of the network, packets are assigned a label by a label edge router (LER). Packets are forwarded along an label-switched path (LSP) where each label switch router (LSR) makes forwarding decisions based on the label information. At each hop, an LSR swaps the existing label for a new label that tells the next hop how to forward the packet. At the outgoing (egress) point, an LER removes the label, and forwards the packet to its destination via IP routing.

MPLS enables these applications: Virtual Private Network (VPN), traffic engineering (TE), and Quality of Service (QoS).

See also Label Distribution Protocol (LDP), Resource Reservation Protocol—Traffic Engineering (RSVP-TE).

Multi-Protocol Label Switching - Transport Profile (MPLS-TP). A subset of Multi-Protocol Label Switching (MPLS) with extensions that address transport network requirements. The extensions provide the same QoS, protection and restoration, and Operation, Administration, and Maintenance (OAM) as in SONET/SDH. In MPLS-TP, some of the MPLS functions are turned off, such as penultimate hop popping (PHP), label-switched path (LSP) merge, and equal-cost multipath (ECMP).

The use of a control plane protocol is optional in MPLS-TP. The control plane can set up an LSP automatically across a packet-switched network domain. However, some network operators might prefer to configure the LSPs statically without using an IP or routing protocol.

multicast. The process of a single host sending messages to a selected group of receivers. See also broadcast, unicast.

multicast group. A collection of hosts receiving packets from a host that is transmitting multicast packets. Only hosts that need to hear a particular multicast declare that requirement. A multicast group restricts traffic to just those paths between the sources and destinations associated with the multicast address. Membership is dynamic; when a host joins a group, it starts receiving the datastream, and when a host leaves a group, it stops receiving the datastream. When there are no more members, the group simply ceases to exist.

See also GARP Multicast Registration Protocol (GMRP), Internet Group Management Protocol (IGMP), Multicast Listener Discovery (MLD), Multiple MAC Registration Protocol (MMRP), (S,G).

Multicast Listener Discovery (MLD). An IPv6 protocol that allows hosts to add or remove themselves from a multicast group. Defined by RFC 3810.

See also Internet Group Management Protocol (IGMP), multicast group, (S,G).

Multiple MAC Registration Protocol (MMRP). A protocol that manages multicast group MAC addresses. In addition, MMRP improves the convergence time of GARP Multicast Registration Protocol (GMRP). Defined by 802.1ak.

Multiple Registration Protocol (MRP). A generic registration framework with protocols, procedures, and managed objects for switches to register attributes with other switches in a LAN. Defined by 802.1ak. MRP replaces Generic Attribute Registration Protocol (GARP)

Multiple Spanning Tree Protocol (MSTP). An enhancement to the Rapid Spanning Tree Protocol (RSTP) where a separate spanning tree for can be configured for a VLAN group. Each VLAN group belongs to a multiple spanning-tree instance (MSTI). Several MSTIs can run in an multiple spanning-tree (MST) region, with each region interconnected in a common and internal spanning tree (CIST).

MSTP is backward compatible with both RSTP and Spanning Tree Protocol (STP).

Originally defined in IEEE 802.1s and later merged into 802.1Q.

multiple spanning-tree (MST) region. A collection of interconnected switches that have the same Multiple Spanning Tree Protocol (MSTP) configuration which includes region name, revision number, and VLAN-to-instance map. Each MST region can contain multiple instances of spanning trees. The network administrator must properly configure participating switches throughout the region. All regions are bound together using a common and internal spanning tree (CIST), which creates a loop-free topology across regions. An MST region appears as a single switch to spanning tree configurations outside the region.

multiple spanning-tree instance (MSTI). A group of VLANs in a spanning-tree instance managed by Multiple Spanning Tree Protocol (MSTP) within an multiple spanning-tree (MST) region. Within each MST region, MSTP maintains multiple spanning-tree instances. Each instance has a spanning-tree topology independent of other

spanning-tree instances. An MSTI provides a fully connected active topology for frames belonging to a VLAN. You can assign a VLAN to only one spanning-tree instance at a time.

An internal spanning tree (IST) is a special type of MTSI.

Multiple VLAN Registration Protocol (MVRP). A protocol that manages registration of VLANs, tracking which routers are members of which VLANs and which router interfaces are in which VLAN. MVRP removes routers and interfaces from the VLAN information when they become unavailable. MVRP improves the convergence time of GARP VLAN Registration Protocol (GVRP). Defined by 802.1ak.

N

name resolution. The process of translating an IP address to a name that is easily remembered by a person. In a TCP/IP environment, a name such as www.example.com is translated into its IP equivalent by the Domain Name Service (DNS).

neighbor. An adjacent system reachable by traversing a single subnetwork; an immediately adjacent device. Also called peer. See also adjacency.

Neighbor Discovery Protocol (NDP). An IPv6 protocol that nodes on the same link use to discover each other's presence, determine each other's Link Layer addresses, find routers, and maintain reachability information about the paths to active neighbors. NDP is defined in RFC 2461 and is equivalent to the Address Resolution Protocol (ARP) used with IPv4.

NETCONF (Network Configuration Protocol). A mechanism to install, manipulate, and delete the configuration of network devices. The operations, notifications, and the database contents supported by a particular NETCONF server are extensible, and defined with a modeling language called YANG. The database is used to store YANG data structures which represent the configuration of the device containing the NETCONF server. This configuration can be saved in non-volatile storage so the configuration can be restored upon reboot. Defined in RFC 6241.

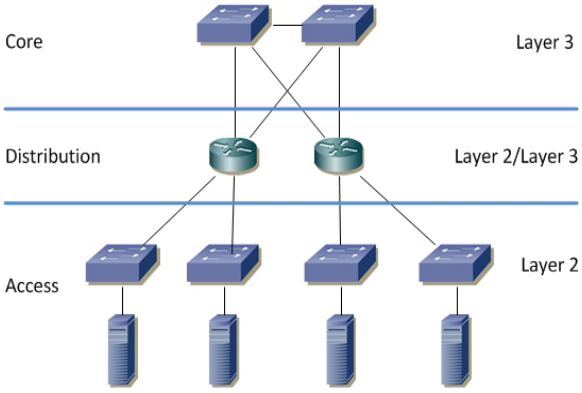
network. A group of computers and related devices connected by a communications channel capable of sharing resources among several users. A network consists of transmission media, devices such as routers or switches, and protocols that make message sequences meaningful.

A network can range from a peer-to-peer network connecting a small number of users in an office or department, to a Local Area Network (LAN) connecting many users, to a wide area network (WAN) connecting users on several networks spread over a wide geographic area.

network address translation (NAT). A method to use one set of IP addresses for an internal inetwork and a second set of addresses for the public Internet. This allows an organization to shield internal addresses from the public Internet. NAT is configured on the router at the border of an internal network and the Internet. NAT translates the internal local addresses to globally unique IP addresses before sending packets to the Internet and vice versa. Defined by RFC 1631.

network administrator. The person responsible for the day-to-day operation and management of a network.

network design model. A hierarchical model originally defined by Cisco that divides a network into three functional areas, or layers. This model optimizes network hardware and software to perform specific roles.



The roles that each layer performs are:

- The access layer provides local user access to the network
- The distribution layer connects network services to the access layer, and implements policies regarding security, traffic loading, and routing
- The core layer provides high-speed transport for the distribution layer

See also collapsed core.

Network Element (NE). Any device in a network such as a host, router, switch, or firewall that performs a service or function for the network.

Network Functions Virtualization (NFV). The ability to decouple network services from dedicated hardware devices to be hosted on a virtual machine (VM). Once the network services are under the control of a hypervisor, the services can be performed on standard x86 servers.

network layer. See Layer 3 (L3).

network segment. A portion of a computer network that is separated from the rest of the network by a device such as a router or switch. Each segment can contain one or more hosts.

Network Services Module (NSM). The base module in OcNOS that communicates with every OcNOS routing and switching process. The protocol components use APIs exposed by the NSM client, which act as conduits to transfer data between the protocol modules and NSM.

Network Time Protocol (NTP). A protocol used to synchronize the system clocks of hosts on a network to Universal Coordinated Time (UTC). A device can update its clock automatically by configuring itself as an NTP client. Using NTP enables the device to record accurate times of events. Defined by RFC 5905.

Neutron. The networking component of OpenStack that provides “networking as a service” between virtual NICs managed by other OpenStack services.

Neutron provides a “plug-in” mechanism that lets network operators enable different technologies. It also lets tenants create multiple private networks and control their IP addressing. Organizations have control over security and compliance policies, Quality of Service (QoS), monitoring and troubleshooting, as well as the ability to deploy network services, such as a firewall, intrusion detection, and Virtual Private Network (VPN) instances.

next hop. The next device to which a protocol data unit (PDU) is sent on its way to its destination.

Next Hop Label Forwarding Entry (NHLFE). An Multi-Protocol Label Switching (MPLS) entry containing next hop information (interface and next hop address) and label manipulation instructions; it can also include label encoding, L2 encapsulation information, and other information to process packets in the associated stream.

node. An addressable device such as a host, router, or switch, attached to a network, that transmits and receives data.

north/south. The flow of traffic traversing between users and a data center (spanning-tree). Contrast with east/west.

northbound. An interface that allows a network component to communicate with a higher-level component. A northbound interface hides complex details of operations. Northbound flow can be thought of as going upward. In architectural diagrams, northbound interfaces are drawn at the top of the component. See also southbound.

Not-So-Stubby-Area (NSSA). An extension of a Open Shortest Path First (OSPF) stub area. OSPF uses an NSSA as a transit to send external routes to other areas or to domains that are not part of the OSPF autonomous system. OSPF does not flood external routes from other areas into an NSSA, but does translate and flood route information from the NSSA into other areas such as the backbone. Defined by RFC 1587.

O

Open Network Foundation (ONF). A non-profit organization responsible for the development and standardization of a software architecture that supports Software-Defined Networking (SDN). ONF is also responsible for the commercialization and promotion of SDN as a concept and its underlying technologies. For more, see: https://www.opennetworking.org/.

Open Shortest Path First (OSPF). An Interior Gateway Protocol (IGP) based on link-state routing. OSPF is widely deployed in large networks because of its efficient use of network bandwidth and its rapid convergence after changes in topology. Defined in RFCs 2328 and RFC 5340.

OSPF advertises the states of local network links within an autonomous system (AS) and makes routing decisions based on the shortest path first (SPF) algorithm. Each OSPF router maintains an identical database describing the autonomous system's topology. From this database, a Routing Information Base (RIB) is calculated by constructing a shortest path tree (SPT).

OSPF features include least-cost routing, multipath routing, and load balancing. OSPF includes explicit support for Classless Interdomain Routing (CIDR) and the tagging of externally derived routing information.

OSPF version 2 supports IPv4 and OSPF version 3 supports IPv6.

OSPF divides an autonomous system into contiguous groups of networks called areas.

- In a standard area, intra-area routes, inter-area routes, and external routes (learned from other routing protocols such as RIP and BGP) are distributed. Inter-area routes and external routes are distributed as summary addresses.
- A backbone area is essentially a standard area which has been designated as the central point to which all other areas connect. A backbone area combines a set of independent areas into an AS and acts as a hub for inter-area transit traffic and routing information distribution. Each non-backbone area is directly connected to the backbone area.
- OSPF uses stub area instances and Not-So-Stubby-Area (NSSA) instances to limit distribution of inter-area routes and external routes.

See also area border router (ABR), autonomous system border router (ASBR).

Open Systems Interconnection (OSI) Reference Model. A conceptual model defined by the International Organization for Standardization (ISO) that organizes the computer-to-computer communications process into seven layers. Each layer provides services to the layer above and receives services from the layer below. Such a set of layers is called a protocol stack.

Layers seven through five manage end-to-end communications between the message source and destination, while layers one through four manage network access:

- Layer 4 (L4) ensures the end-to-end delivery from a source to a destination
- Layer 3 (L3) routes packets of data from source to destination across a network
- Layer 2 (L2) reliably transports data across the physical link between two directly connected nodes
- Layer 1 (L1) conveys the bit stream at the electrical and mechanical level

The OSI Reference Model is often compared to the more descriptive (versus prescriptive) Transmission Control Protocol/Internet Protocol (TCP/IP) model.

Open vSwitch (OVS). A software switch used in virtualized server environments that forwards traffic between different virtual machine (VM) instances on the same physical host and between VMs and the physical network. OVS enables network automation through programmatic extension, while still supporting standard management interfaces and protocols. For more, see http://openvswitch.org/.

OpenFlow. An open standard for forwarding plane operations that enables researchers to run experimental protocols. OpenFlow is developed, specified, and sponsored by the Open Network Foundation (ONF). OpenFlow provides a protocol that enables a controller to dynamically program internal flow-tables in devices. Network vendors have added OpenFlow features to routers and switches.

OpenStack. A cloud operating system that controls pools of compute, storage, and networking resources in a data center which users manage through a Web-based dashboard, command-line tools, or a RESTful API. See also Neutron.

Operation, Administration, and Maintenance (OAM). A set of Ethernet specifications that provide connectivity monitoring, fault detection and notification, fault verification, fault isolation, loopback, and remote defect identification. The primary specifications are 802.3ah link-fault management (LFM) and 802.1ag Connectivity Fault Management (CFM).

P

packet. A protocol data unit (PDU) at Layer 3 (L3) of the Open Systems Interconnection (OSI) Reference Model. A packet contains source and destination addresses, user data, and control information such as the length of the packet, the header checksum, and flags indicating whether the packet has been fragmented. The user data in a packet is often referred to as the payload. The actual format of a packet depends on the protocol that creates the packet.

A packet sent through a connectionless protocol such as User Datagram Protocol (UDP) is sometimes called a datagram.

See also frame, packet switching.

packet switching. A data-transmission method that transmits information over one of several routes. Information is sent to the destination through the best route, determined by a routing algorithm.

A packet switched network breaks information to be transmitted into discrete packets. Related packets might not all follow the same path to their destination. Packet sequence numbers are used to reassemble the original message at the destination.

A packet-switched network is connectionless because each packet contains its destination address and does not require a dedicated path to reach that destination. Multiple users may transmit packets over the same connection at the same time, independent of one another.

The Internet is an example of a packet-switched network.

Contrast with circuit switching.

paravirtualized. A software component that is aware that it is running in a virtual machine (VM). For example, a paravirtualized virtual device driver runs in a VM that communicates with the underlying host OS. Typically, a paravirtualized driver is optimized to share queues, buffers, or other data items with the underlying host OS to improve throughput and reduce latency.

path computation element (PCE). An entity (component, application, or server) that can compute a network path or route based on a network graph and constraints (see RFC 4655).

path-vector routing. A routing technique that advertises a network as a destination address and a complete path to reach that destination. Each entry in the Routing Information Base (RIB) contains the destination network, the next router, and the path to reach the destination.

A path vector protocol guarantees loop-free paths by recording each hop the routing advertisement traverses through the network. A node can easily detect a loop by looking for its own node identifier in the path.

This technique is sometimes used in Bellman-Ford algorithm to avoid count-to-infinity problems.

Border Gateway Protocol (BGP) is an example of a prefix-based path-vector protocol where the Routing Information Base (RIB) maintains the autonomous systems to traverse to reach a destination.

peer. Immediately adjacent device with which a protocol relationship has been established. Also called neighbor.

penultimate hop popping (PHP). A technique where the outermost label of an Multi-Protocol Label Switching (MPLS) packet is removed by a label switch router (LSR) before the packet is passed to an adjacent label edge router (LER).

physical layer. See Layer 1 (L1).

ping (packet internet groper). A command used to test network connectivity by transmitting an Internet Control Message Protocol (ICMP) diagnostic packet to a specific node on the network, forcing the node to acknowledge that the packet reached the correct destination. If the node responds, the link is operating; if not, something is wrong.

The word ping is often used as a verb, as in “ping that workstation to see if it is alive.”

policing. Applying rate limits on bandwidth and burst size for traffic for a particular interface.

policy-based routing (PBR). Classifying packets to determine their forwarding path within a device. PBR is used to redirect traffic for analysis. Also called filter-based forwarding (FBF).

port. The point at which a communications circuit terminates on a network. A port can be logical, physical or both. Examples include:

- The physical interface between a device and a communications circuit, usually identified by a number or name.
- The logical interface between a TCP/IP applications and a communications facility which use well-known port numbers such as FTP: 20, HTTP: 80, and NFS: 2049.
- The logical interface between a process and a communications facility that allows more than one logical port to be associated with one physical port. For example, Ethernet uses multiple MAC addresses to distinguish between separate logical channels connecting two ports on the same physical transport network interface.

Also called interface.

Precision Time Protocol (PTP). A protocol that synchronizes clocks throughout a computer network. On a LAN, PTP achieves clock accuracy in the sub-microsecond range, making it suitable for measurement and control systems. The time synchronization is achieved through packets that are transmitted and received in a session between a master clock and a slave clock. Defined by IEEE 1588v2.

Priority-based Flow Control (PFC). A flow control mechanism that can be set independently for each frame priority on full-duplex links. Defined by IEEE 802.1Qbb.

private VLAN (PVLAN). A switch with ports that cannot communicate with each other, but can access other networks. A PVLAN has at least one private port and a trunk port. All traffic received on a private port is forwarded out the trunk port. All traffic received on a trunk port is handled as normal switch traffic. No traffic communication occurs between the private ports.

protocol. A set of rules that end points in a network connection must follow when they communicate. A protocol includes data representation, data item ordering, message formats, message and response sequencing rules, block data transmission conventions, and timing requirements.

The Open Systems Interconnection (OSI) Reference Model and Transmission Control Protocol/Internet Protocol (TCP/IP) are both used as a model for many protocols. There are one or more protocols at each layer in the models that both ends of the connection must recognize and observe.

protocol data unit (PDU). A unit of data transmitted as a composite by a protocol.

In the Open Systems Interconnection (OSI) Reference Model, the actual name used for a PDU depends on the layer:

- Layer 4 (L4): segment
- Layer 3 (L3): packet
- Layer 2 (L2): frame
- Layer 1 (L1): stream, symbol stream, or bit stream

See also bridge protocol data unit (BPDU). Sometimes called datagram.

Protocol Independent Multicast (PIM). A method to determine the best paths for distributing a multicast transmission. PIM uses unicast routing tables (such as those used by Open Shortest Path First (OSPF) and Border Gateway Protocol (BGP)) and static routes to perform multicasting. Each host must be registered using IGMP to receive the transmission.

PIM has these variations:

- PIM dense mode (PIM-DM: RFC 3973) uses a push model. PIM-DM initially floods multicast traffic throughout the network. Routers that have no downstream neighbors prune back the unwanted traffic. This process repeats periodically.
- PIM sparse mode (PIM-SM: RFC 4601) uses a pull model. PIM-SM uses a shortest path tree (SPT) where sources forward multicast packets to a designated router which unicasts the packets to an assigned rendezvous point router, which then forwards the packets to members of multicast groups.
- PIM source-specific multicast (PIM-SSM: RFC 3569) uses PIM-SM functionality to create a SPT between the client and the source without using a rendezvous point.
- Bidirectional PIM (Bidir-PIM: RFC 5015) uses PIM-SM functionality to route traffic only along a bidirectional SPT that is rooted at the rendezvous point for a group.

protocol stack. The layers of software used in network communications.

Provider Backbone Bridge-Traffic Engineering (PBB-TE) . An extension to Provider Backbone Bridging (PBB) that removes features such as flooding, dynamically created forwarding tables, and spanning tree protocols. PBB-TE also covers Connectivity Fault Management (CFM) and Ethernet Linear Protection Switching (ELPS).

In PBB-TE, a network administrator configures the forwarding tables in the backbone switches with static routes to ensure that frames take predetermined paths within the network. Frames with destination MAC addresses not in a forwarding table are dropped. Broadcast frames are not supported and are also dropped by backbone switches.

Defined in IEEE 802.1Qay.

Provider Backbone Bridging (PBB). A technique to create Ethernet backbones for service access networks. Defined in IEEE 802.1ah, PBB extends Provider Bridging (PB) defined in 802.1ad in these ways:

- The 802.1ah header adds an I-SID (Service Instance Identifier) which is a label that maps to a customer VLAN identifier. An I-SID virtualizes VLANs across a network. VLANs are mapped into I-SIDs by configuring only the edge of the network at a backbone edge bridge (BEB). This makes the maximum number of service instances 16 million.
- The 802.1ah header encapsulates backbone source and destination MAC addresses (B-MAC) along with the customer source and destination MAC addresses (C-MAC). The B-MAC contains MAC addresses of the service provider's PBB edge switches. The 802.1ah format is sometimes called “MAC-in-MAC” because of this MAC address encapsulation. The encapsulation of customer MAC addresses in backbone MAC addresses means that the backbone does not need to learn customer MAC addresses. Customer MAC addresses are learned at BEB ports only.

Provider Bridging (PB). A technique that enables a service provider to use the architecture and protocols of 802.Q to offer the equivalent of separate LANs, bridged LANs, or VLANs to multiple customers. Provider bridging requires no active cooperation between customers and requires minimal cooperation between an individual customer and the service provider.

When VLANs were originally defined in 802.1Q, the number of unique VLAN identifiers was limited to 4096. In large provider networks, each subscriber needs a separate address, so this limit could prevent a provider from having more than 4096 subscribers.

To overcome this limit, 802.1ad inserts an additional VLAN tag into a single 802.1Q Ethernet frame. Frames passing through the provider network are doubly tagged with:

- customer VLAN (C-VLAN) tag which identifies the customer network VLAN
- service VLAN (S-VLAN) tag which identifies the service provider network VLAN

With two VLAN identifiers in combination for each provider-customer pair, it is possible to define up to 16,777,216 VLANs.

The frame format for 802.1ad is also called Q-in-Q, double tagged, stacked VLANs, or VLAN stacking.

provider edge (PE). A device at the edge of an enterprise or service provider core network. A PE offers an initial, first level of network traffic aggregation for many customer edge (CE) devices.

pseudowire (PW). An emulation of a point-to-point connection over a packet-switching network. A pseudowire is a way to transport legacy services such as TDM over a packet-switched network:

- Structure-aware TDM circuit emulation service over packet-switched network (CESoPSN)
- Structure-agnostic TDM over packet (SAToP)

A pseudowire that both originates and terminates on the edge of a single packet-switched network (autonomous system or carrier network) is called a single-segment pseudowire (SS-PW). A pseudowire that extends through multiple autonomous systems or carrier networks is called a multi-segment pseudowire (MS-PW).

Q

Q-in-Q. See Provider Bridging (PB).

QEMU (Quick EMUlator). A hosted hypervisor that performs hardware virtualization. QEMU emulates CPUs through dynamic binary translation and provides a set of device models enabling it to run a variety of unmodified guest operating systems. QEMU also can be used together with KVM (Kernel-based Virtual Machine) to run virtual machines at near-native speed (requiring hardware virtualization extensions on x86 machines). QEMU can also be used purely for CPU emulation for user-level processes, allowing applications compiled for one architecture to be run on another.

Quality of Service (QoS). The ability to *guarantee* the delivery, control the bandwidth, set priorities for specific network traffic, and provide an appropriate level of security. QoS provides a level of predictability and control beyond the best effort delivery that a device provides by default.

See also Class of Service (CoS).

Quantized Congestion Notification (QCN). An end-to-end congestion management scheme for protocols capable of transmission rate limiting. Defined by IEEE 802.1Qau.

R

radio access network (RAN). The air interface and base station technology in a cellular network. In addition to the RAN, the entire cellular system includes the core network, which provides the backbone and services, as well as the cellphones.

Rapid Per-VLAN Spanning Tree Plus (RPVST+). A version of Cisco Per VLAN Spanning Tree Plus (PVST+) that uses the Rapid Spanning Tree Protocol (RSTP) state machine. PVST+ runs a spanning tree instance for each VLAN in the network. PVST+ is not scalable when there are many VLANs in a network. A compromise between RSTP and R-PVST+ is Multiple Spanning Tree Protocol (MSTP) which runs multiple instances of spanning tree that are independent of VLANs. MSTP maps a set of VLANs to each spanning tree instance.

Rapid Spanning Tree Protocol (RSTP). An enhancement to the Spanning Tree Protocol (STP) that re-configures quickly after a topology change. RSTP can verify if a port can change to a forwarding state safely without waiting for timers to start convergence. RSTP is not aware of VLANs and blocks ports at the physical level. Defined by IEEE 802.1D. See also Multiple Spanning Tree Protocol (MSTP).

Remote Authentication Dial In User Service (RADIUS). An authentication and accounting protocol to authenticate users and authorize their access to the requested system or service.

Defined in RFCs 2058, 2059, and 2865. See also authentication, authorization, and accounting (AAA), Lightweight Directory Access Protocol (LDAP), Terminal Access Controller Access Control System Plus (TACACS+).

remote monitoring (RMON). A Management Information Base (MIB) specification that defines functions for remotely monitoring networked devices. The RMON specification provides many problem detection and reporting capabilities. Defined by RFC 2819.

Request for Comments (RFC). Proposals and standards that define protocols for communications over the Internet. RFCs are developed and published by the Internet Engineering Task Force (IETF).

Resource Reservation Protocol (RSVP). A signalling protocol for reserving resources across a network. RSVP is rarely used by itself, but Resource Reservation Protocol—Traffic Engineering (RSVP-TE) is widely used.

Resource Reservation Protocol—Traffic Engineering (RSVP-TE). RSVP with traffic engineering extensions, as defined by RFC 5101, that allows RSVP to establish label-switched path (LSP) instances in Multi-Protocol Label Switching (MPLS) networks, using Constrained Shortest Path First (CSPF), taking into consideration constraints such as available bandwidth and explicit hops. The LSPs might not agree with the route suggested by the Open Shortest Path First (OSPF) or Intermediate System to Intermediate System (IS-IS).

reverse path forwarding (RPF). An algorithm that checks the unicast Routing Information Base (RIB) to determine whether there is a shortest path back to the source address of an incoming multicast packet. Unicast RPF helps determine the source of denial-of-service attacks and rejects packets from unexpected source addresses.

Rivest-Shamir-Adleman (RSA). A public key, or asymmetric, encryption scheme. The oretical background to RSA is that it is difficult to find the factors of a very large number that is the product of two prime numbers. RSA is considered very secure provided a sufficiently long key is used.

route. The path from source to destination through a network.

route flap damping. Method for minimizing instability caused by route flapping. The router stores a penalty value for each route. Each time the route flaps, the router increases this value. If the penalty for a route reaches a configured suppress value, the router does not include the route as a forwarding entry and does not advertise the route to peers.

route redistribution. One protocol learning routes from another protocol running on the same device. Also called redistribution or route leakage.

route reflection. A method of allowing iBGP routers to accept and propagate iBGP routes to their clients.

To avoid routing loops, Border Gateway Protocol (BGP) does not advertise routes learned from an internal BGP peer to other internal BGP peers. Instead, BGP requires that all internal peers be fully meshed so that any route advertised by one router is advertised to all peers within the autonomous system (AS). As a network grows, the full mesh requirement becomes difficult to manage. To handle scaling problems, BGP uses route reflection and BGP confederations.

Route reflection allows you to designate one or more routers as route reflectors. BGP relaxes the re-advertising restriction on route reflectors, allowing them to accept and propagate iBGP routes to their clients.

route summarization. Consolidating multiple routes into a single route advertisement, in contrast to flat routing where a Routing Information Base (RIB) contains a unique entry for each route.

Classless Interdomain Routing (CIDR) is used to implement route summarization. All IP addresses in the route advertisement must have identical high-order bits.

Also called route aggregation. See also subnet mask.

router. A Layer 3 (L3) device that makes decisions about the paths over which network traffic will flow. Routers use dynamic routing protocols to learn about the network and to find the best route to forward packets toward their final destination:

1. Find a matching destination address in the Routing Information Base (RIB)
2. Find the MAC address for the packet from the Address Resolution Protocol (ARP) cache
3. Write the new MAC address in the IP packet
4. Send the packet on the port associated with the MAC address

routing. The process of finding a path to a destination to use to transmit a protocol data unit (PDU) over a network. Routing is usually controlled by a Routing Information Base (RIB) which defines where a PDU should go. Each router only needs to know where a PDU should be sent on its next hop, and does not know nor care what happens afterward; the next hop plus one is the responsibility of the next router, and so on through the network until a PDU reaches its destination.

Routing Information Base (RIB). A data structure in a device that lists the routes to destinations and metrics (distances) associated with those routes. A RIB contains information about the topology of the network immediately around it. Maintaining a RIB by discovering network topology is the primary purpose of dynamic routing protocols such as Border Gateway Protocol (BGP), Routing Information Protocol (RIP), and Open Shortest Path First (OSPF). Network administrators can also add fixed routes to the RIB for static routing.

Also called a routing table. Contrast with Forwarding Information Base (FIB).

Routing Information Protocol (RIP). An Interior Gateway Protocol (IGP) that implements a distributed variant of the Bellman-Ford algorithm to provide distance-vector routing capabilities. RIP uses the hop count of a destination to detect the best path to route packets, but limits the maximum number of hops to 15 to prevent routing loops. RIP implements split horizon techniques. Defined in RFC 1058.

RIP is easy to configure and has low processing requirements. However, the hop count limit restricts the size of the network that RIP can support. Also, RIP can be slow to converge.

RIPv2 defined in RFC 2453 also supports subnet information, allowing Classless Interdomain Routing (CIDR).

RIPng (next generation), an extension of RIPv2 defined in RFC 2080, supports IPv6.

routing protocol. A set of processes, algorithms, and messages that are used to exchange routing information and populate the local Routing Information Base (RIB) with the best path between a source and destination.

The term “routing protocol” usually implies dynamic routing, where a device reports changes and shares information with other devices in the network. Each router starts with knowledge of only the devices to which it is directly attached. The routing protocol shares this information first with its immediate neighbors, and then throughout the network. This way, routers learn the topology of the network.

A primary benefit of dynamic routing protocols over static routing is that routers exchange information when there is a topology change. This exchange allows routers to automatically learn about new devices and networks and also to find alternate paths when there is a link failure in the current network.

Table 13-103 summarizes the characteristics of the dynamic routing protocols supported by OcNOS:

Table 13-103: Dynamic routing protocols

	Border Gateway Protocol (BGP)	Routing Information Protocol (RIP)	Open Shortest Path First (OSPF)	Intermediate System to Intermediate System (IS-IS)
Algorithm	path-vector routing	distance-vector routing	link-state routing	link-state routing
Type	Exterior Gateway Protocol (EGP)	Interior Gateway Protocol (IGP)	Interior Gateway Protocol (IGP)	Interior Gateway Protocol (IGP)
Classless Interdomain Routing (CIDR)	Yes	RIP v1: No RIP v2: Yes	Yes	Yes
Scalable	Yes	No	Yes	Yes
Speed of convergence	Moderate	Slow	Fast	Fast

Table 13-103: Dynamic routing protocols

	Border Gateway Protocol (BGP)	Routing Information Protocol (RIP)	Open Shortest Path First (OSPF)	Intermediate System to Intermediate System (IS-IS)
Resource Use	High	Low	High	High
Configuration ease	Complex	Simple	Complex	Complex

routing table. See Routing Information Base (RIB).

S

S-TAG. See service VLAN (S-VLAN).

(S,G). A notation used in multicast that enumerates a shortest path tree (SPT) where:

- S is the IP address of the source
- G is the multicast group address that identifies the receivers

If the IP address of the source is 192.1.1.1, and the IP address of the multicast group is 224.1.1.1, the source group is written as (192.1.1.1, 224.1.1.1).

Secure Shell (SSH). A protocol that allows the opening of a secure, encrypted channel between two computers with secure authentication. SSH is most often used to provide a secure shell to log in to a remote machine, but also supports file transfers, TCP, and other functions.

segment routing. A form of source routing where nodes and links are represented as segments. The path that a particular protocol data unit (PDU) needs to traverse is represented by one or more segments.

server. A system entity that provides a service to other entities called clients.

service VLAN (S-VLAN). In a Provider Bridging (PB) frame, a tag that identifies the service provider network VLAN. See also customer VLAN (C-VLAN). Also called an S-TAG or S-VID tag.

Shortest Path Bridging (SPB). A control plane protocol that combines an Ethernet data path with an Intermediate System to Intermediate System (IS-IS) link state protocol running between switches. SPB does not depend on spanning tree protocols to provide a loop-free topology, but instead uses IS-IS link-state packets to discover and advertise the network topology and compute the shortest path tree (SPT) instances from all bridges in the SPB area. SPB only requires provisioning at the edge of the network. Defined by IEEE 802.1aq, with RFC 6329 describing the IS-IS extensions to support SPB.

There are two types of SPB depending on the type of Ethernet data path:

- Shortest Path Bridging - VID (SPBV) uses a Provider Bridging (PB) (802.1ad) data path
- Shortest Path Bridging - MAC (SPBM) uses a Provider Backbone Bridging (PBB) (802.1ah) data path

shortest path first (SPF). Algorithm used by Intermediate System to Intermediate System (IS-IS) and Open Shortest Path First (OSPF) to make routing decisions based on the state of network links. Also called the Dijkstra algorithm.

shortest path tree (SPT). A Routing Information Base (RIB) formed by using the shortest path first (SPF) algorithm.

shortest-path routing. A routing algorithm in which paths to all network destinations are calculated. The shortest path is then determined by a cost assigned to each link.

signalling. The ability to transfer information within a network or between different networks.

Simple Network Management Protocol (SNMP). A standardized framework for monitoring and managing devices in a network. The SNMP framework consists of three parts:

- SNMP manager: The system used to control and monitor the activities of network devices.
- SNMP agent: The component within a managed device that maintains the data for the device and reports the data SNMP managers.
- Management Information Base (MIB): How SNMP exposes data as variables which describe the system configuration. These variables can be queried (and sometimes set) by SNMP managers.

SNMP uses User Datagram Protocol (UDP) to send and receive messages on the network.

Single Root I/O Virtualization (SR-IOV). A specification that allows a single Peripheral Component Interconnect Express (PCIe) physical device under a single root port to appear to be multiple separate physical devices to the hypervisor or the guest operating system.

SR-IOV uses physical functions (PFs) and virtual functions (VFs) to manage global functions for the SR-IOV devices:

- PFs are used to configure and manage the SR-IOV functionality
- VFs are lightweight and contain all the resources necessary for data movement but have a minimal set of configuration resources

SR-IOV enables network traffic to bypass the software switch layer of a virtualization stack. The I/O overhead in the software emulation layer is nearly the same as in nonvirtualized environments.

Software-Defined Networking (SDN). An approach to designing, building, and operating networks that decouples the control plane from the data plane. The control plane is centralized in the form of a controller system. Communication between the controller system and the network device uses a standard protocol such as OpenFlow or other agents. The controller system can consist of multiple, domain specific, clustered controllers. An SDN architecture usually includes APIs that developers use to control the underlying network. These APIs can be standards-based, or they can be vendor-specific.

source routing. A technique where the sender of a protocol data unit (PDU) can partially or completely specify the route that the PDU should take through the network. See also segment routing.

southbound. An interface that allows a network component to communicate with a lower-level component. A southbound interface breaks down the concepts into smaller technical details that are specifically geared toward the lower-layer component within the architecture. Southbound flow can be thought of as going downward. In architectural diagrams, southbound interfaces are drawn at the bottom of the component. See also northbound.

spanning tree algorithm. A technique that finds the best path between segments of a multilooped, mesh network. If multiple paths exist in the network, the spanning tree algorithm finds the most efficient path and limits the link between the two networks to this single active path. If this path fails because of a cable failure or other problem, the algorithm reconfigures the network to use another path.

From the point of view of an individual switch, a spanning tree has a root node and one path that connects all the other switches.

Spanning Tree Protocol (STP). A protocol that creates spanning trees within mesh networks of connected devices, disabling any links that are not a part of the tree and leaving a single active connection between any two unique network nodes. Defined by 802.1D.

STP devices exchange bridge protocol data unit (BPDU) messages. The spanning tree algorithm calculates the best path and prevents multiple paths between network segments. STP elects a root bridge, finds paths and determines the least cost path to the root bridge, then disables all other paths.

Network managers can set up redundant links as backups in case active links fails. Automatic backup takes place without the pitfalls of bridge loops or the need to manually enable or disable backup links.

See also Rapid Spanning Tree Protocol (RSTP) and Multiple Spanning Tree Protocol (MSTP).

split horizon. A technique where routes learned from an interface are not advertised on that same interface, preventing the router from seeing its own route updates.

In split horizon with poison reverse, routes learned from an interface are set as unreachable and advertised on that same interface which also prevents the router from seeing its own route updates.

stacked VLAN. See Provider Bridging (PB).

static address. An address permanently assigned to a device. Contrast with a dynamic address.

static routing. A method where a network administrator programs connecting paths between networks into a router. If a connection fails, the administrator must reprogram the router to use a new path. Static routes have precedence over routes chosen by dynamic routing protocols.

stub area. A type of Open Shortest Path First (OSPF) area where external routes are distributed as a single default route (address 0.0.0.0). Inter-area routes are distributed in a stub area as summary addresses.

In a *totally stubby area*, a single default route is distributed for all external *and* inter-area routes. Addresses from both other areas and external networks are distributed as the default route (address 0.0.0.0).

See also Not-So-Stubby-Area (NSSA).

subnet mask. A bit pattern that shows how an Internet address is divided into network, subnetwork, and host parts. The mask has ones in the bit positions to be used for the network and subnet parts, and zeros for the host part. The mask should contain at least the standard network portion, and the subnet field should be contiguous with the network portion.

This is an example is this IPv4 address and subnet mask:

192.168.100.12 with subnet mask of 255.255.255.0

The first 24 bits of the address is the network address (192.168.100.0) and the last 8 bits are the hosts (12). The entire subnet spans the address range 192.168.100.0 to 192.168.100.255.

The addresses on a given subnet are always contiguous and can all be derived from the network address. Bit masks are always with respect to binary digits, so the number of IP addresses on a given subnet is always some power of two.

A mask gives the first address in the block (the network address) when ANDed with an address in the block.

Classless Interdomain Routing (CIDR) represents the equivalent of a subnet mask by adding a prefix length to an IP address that is the number of bits in the network portion. For example, the subnet mask above can be written as:

192.168.100.12/24

where 192.168.100.12 is the IP address and /24 is the number of bits in the subnet mask.

A subnet mask represents the same information as a prefix length, but predates the use of CIDR.

Also called address mask, network mask.

subnetwork. A group of related IP addresses that all begin with the same network portion and end with a unique portion identifying the host within the subnet.

Also called subnet. See also subnet mask.

subsequent address family identifier (SAFI). Number that further identifies an address family.

supernetting. The process of taking several discrete network addresses and advertising them as one route. For example, if an organization is using 192.10.1.0/24 to 192.10.254.0/24, instead of advertising 254 separate networks, the organization can advertise only the single route 192.10.0.0/16.

switch. A Layer 2 (L2) device that forwards frames based on a destination MAC address. A switch finds a destination address in its filtering database and transmits the frame on the port associated with the destination address. The filtering database is populated through a self-learning process, where each incoming frame is used to update the entries in the filtering database.

A switch that is VLAN-aware can also forward frames based on VLAN identifiers. A network administrator can configure this mapping manually or a switch can dynamically learn mappings via GARP VLAN Registration Protocol (GVRP).

Basic switch behavior is defined in IEEE 802.1D and 802.1Q.

See also bridge. Contrast with router.

Synchronous Ethernet (SyncE). SONET/SDH/PDH-based synchronization that is used to synchronize and send frequency information to devices on an Ethernet network. Synchronous Ethernet provides only frequency synchronization, not time or phase synchronization.

T

telnet. A client/server protocol that establishes a session between a user terminal and a remote host:

- The telnet client software takes input from the user and sends it to the server's operating system
- The telnet server takes output from the host and sends it to the client to display to the user

While telnet is most often used to implement remote login capability, the protocol is general enough to allow it to be used for a variety of purposes.

Terminal Access Controller Access Control System Plus (TACACS+). An authentication method that provides access control for networked devices using one or more centralized servers. TACACS+ provides separate authentication, authorization, and accounting (AAA) services. (Usually pronounced like tack-axe.)

See also Lightweight Directory Access Protocol (LDAP), Remote Authentication Dial In User Service (RADIUS).

throughput. Average rate of successful delivery of data packets over a communication link. Throughput is measured in bits per second, data packets per second, or sometimes data packets per time slot. See also line rate, latency, wire speed.

time to live (TTL). A limit on how long a piece of information can exist before it should be discarded. TTL is a field in an IP header that is (usually) decremented by 1 for each hop through which the packet passes. If the field reaches zero, the packet is discarded, and a corresponding error message is sent to the source of the packet.

Top-of-Rack (ToR) switch. In a data center, an access layer switch that connects to servers installed in the same rack. A ToR switch is usually low profile (one or two rack units in height) with a low port count (typically 48 ports). All cabling for servers stays within the rack as relatively short cables from the servers to the switch. The switch connects

the rack to the data center network with one fiber uplink to a distribution layer switch. There is no need to run cabling between racks and each rack can be managed as a modular unit.

A ToR switch extends the Layer 2 (L2) topology from the aggregation switch to each individual rack resulting in a larger Layer 2 footprint.

See also end-of-row switch.

topology. The physical or logical layout of a network.

topology change notification (TCN). In Spanning Tree Protocol (STP), a bridge protocol data unit (BPDU) that a switch sends to signal a topology change.

traffic engineering (TE). The ability to control the path taken through a network based on a set of traffic parameters. Traffic engineering optimizes the performance of networks and their resources by balancing traffic load across links, routers, and switches in the network. See also Resource Reservation Protocol—Traffic Engineering (RSVP-TE).

Transmission Control Protocol (TCP). A Layer 4 (L4) protocol that works above Internet Protocol (IP) and provides reliable data delivery over connection-oriented links.

TCP splits the stream of data into packets with a sequence number, and sends the packets over an IP-based network. At the destination, TCP acknowledges packets that have been received (so that missing packets can be resent) and reassembles received packets in the correct order to provide an in-order data stream to the remote application. If TCP detects a missing, corrupted, or out of order packet, it requests it be resent from the source.

See also Transmission Control Protocol/Internet Protocol (TCP/IP), User Datagram Protocol (UDP).

Transmission Control Protocol/Internet Protocol (TCP/IP). A family of Internet protocols that describe how data should be formatted, addressed, transmitted, routed, and received to enable computers to communicate over a network.

The Open Systems Interconnection (OSI) Reference Model is a more prescriptive (versus descriptive) approach to network design. TCP/IP does not map cleanly to the OSI model because it was developed before the OSI model and was designed to solve a specific set of problems, not to be a general description for all network communications.

TCP/IP is a widely published open standard and is supported by many vendors and is available on many different computers running many different operating systems. TCP/IP is separated from the network hardware and will run over Ethernet and other connections.

TCP/ IP also refers to the specific functionality at layers 4 and 3:

- Transmission Control Protocol (TCP) at Layer 4 (L4) splits a message into packets that are transmitted over the Internet and reassembles the packets into the original message at the destination
- Internet Protocol (IP) at Layer 3 (L3) addresses and routes each packet so that it gets to its destination

transport layer. See Layer 4 (L4).

tunneling. A method of transporting data in one protocol by encapsulating it in another protocol. Tunneling is used for reasons of incompatibility, implementation simplification, or security. For example, a tunnel lets a remote VPN client have encrypted access to a private network.

type of service (ToS). A field in the IPv4 header used to differentiate packet flows. See also Differentiated Services (DiffServ).

type-length-value (TLV). A data structure used to encode optional information in a data communications protocol:

- Type: the kind of field that this part of the message represents

- Length: the size of the value field, usually in bytes
- Value: a variable-sized set of bytes that contains the data of the message

U

unicast. The process of a single host sending messages to one destination.See also broadcast, multicast.

User Datagram Protocol (UDP). A connectionless transport layer protocol that exchanges datagrams without acknowledgments or guaranteed delivery and which requires other protocols to handle error processing and retransmission. Defined in RFC 768.

Multicast applications that deliver audio and video streams use UDP as their delivery mechanism because the acknowledgment and retransmission services offered by Transmission Control Protocol (TCP) are not needed and add too much overhead.

User-to-Network Interface (UNI). The physical interface/demarcation between a service provider and a subscriber, the service start or end point. There are two types of UNI:

- UNI-C: customer-side processes
- UNI-N: network-side processes

V

VirNOS. An IP Infusion product based on Network Functions Virtualization (NFV) that helps network operators deploy and manage networking services. Many core networking services, including switching, routing, load balancing and VPN can be performed by software either running directly on x86-64 servers or running as virtual machine (VM) instances instead of requiring expensive networking equipment. Therefore, organizations are migrating networking functions to standard, high-volume server environments and replacing dedicated network hardware with virtualization software that runs on commodity servers. Carriers, service providers, enterprises and network equipment manufacturers can run VirNOS as-is, on top of a standard server platform. IP Infusion customers can integrate VirNOS into their software offering and thereby add services and features quickly.

Virtual Ethernet Bridge (VEB). A virtual switch implemented in a virtualized server environment. A VEB mimics a traditional external Layer 2 (L2) switch for connecting to a virtual machine (VM). VEBs can communicate between VMs on a single physical server, or they can connect VMs to the external network. The most common implementations of VEBs are software-based vSwitches built into hypervisors.

Virtual Local Area Network (VLAN). A logical group of network devices that appear to be on the same LAN, regardless of their physical location. VLANs enable multiple bridged LANs to transparently share the same physical network link while maintaining isolation between networks. Traffic between VLANs is restricted to devices that forward unicast, multicast, or broadcast traffic only on the LAN segments that serve the VLAN to which the traffic belongs.

VLANs make it easy to administer logical groups of hosts that can communicate as if they were on the same LAN.

Membership in a particular VLAN can be by port, MAC address, protocol, or subnet.

VLANs are configured as unique Layer 2 (L2) broadcast domains. VLANs allow network administrators to resegment their networks without physically rearranging the devices or network connections. VLANs span one or more ports on multiple devices and several VLANs can co-exist on a single physical switch. By default, each VLAN maintains its own filtering database containing MAC addresses learned from frames received on ports belonging to the VLAN.

IEEE 802.1Q provides for tagging Ethernet frames with VLAN identifiers. 802.1Q only supports up to 4094 VLANs, which is a scaling constraint for service providers.

virtual machine (VM). An operating system or application environment installed on emulated hardware and not physically installed on dedicated hardware. The virtual machine's guest operating system does not have to be modified to run in a virtualized environment. A VM behaves like a traditional, physical server and runs a traditional operating system such as Windows or Linux.

A hypervisor emulates the computer's CPU, memory, hard disk, network and other hardware resources completely, enabling virtual machines to share the resources. The hypervisor can emulate multiple virtual hardware platforms that are isolated from each other. For example, virtual machines can run Linux and Windows operating systems and share the same underlying physical host. An operating sysem is unaware that it is running in a VM.

See also paravirtualized, virtualization.

virtual port. A port on a vSwitch (Virtual Switch) where virtual Ethernet adapters or physical uplinks can be attached. During their creation, virtual switches are typically configured with a specific number of virtual ports.

virtual private LAN service (VPLS). Multipoint-to-multipoint Layer 2 (L2) VPN service used to interconnect multiple Ethernet LANs across an Multi-Protocol Label Switching (MPLS) backbone.

VPLS evolved as a logical extension of Virtual Private Wire Service (VPWS) based on RFC 4447.

VPLS can be defined as several instances of a virtual switch instance (VSI) that are interconnected to form a single logical bridge domain.

Virtual Private Network (VPN). A network service which uses encryption and tunneling to provide a subscriber with a secure private network that runs over the public network infrastructure.

Virtual Private Wire Service (VPWS). Point-to-point Layer 2 (L2) VPN service used to interconnect multiple Ethernet LANs across an Multi-Protocol Label Switching (MPLS) backbone. Also called Virtual Leased Line (VLL) or Ethernet over MPLS (EoMPLS).

virtual router (VR). A OcNOS proprietary abstraction where multiple distinct logical routers exist within a single device. Each virtual router executes separate instances of the routing protocol and network management software. A virtual router provides support for multiple Routing Information Base (RIB) instances and multiple Forwarding Information Base (FIB) instances per physical router. Each VR might consist of an Open Shortest Path First (OSPF), Border Gateway Protocol (BGP), or Routing Information Protocol (RIP) routing process, each with its own Routing Information Base (RIB) and Forwarding Information Base (FIB). Applications include segregating traffic dedicated to different customers, enterprise Virtual Private Network (VPN) users, or a specific traffic type such as streaming video.

Do not confuse a Virtual Router Redundancy Protocol (VRRP) virtual router with a OcNOS virtual router. They are two different things.

Virtual Router Redundancy Protocol (VRRP). A protocol that uses a *virtual router*, an abstract representation of multiple routers (master and backup routers) that act as a group. VRRP advertises a virtual router as the default gateway instead of one physical router. Two or more physical routers are configured, with only one doing the actual routing at any given time. If the current physical router that is routing on behalf of the virtual router fails, the other physical router automatically takes over. Defined by RFC 5798.

Do not confuse a VRRP virtual router with an OcNOS virtual router (VR). They are two different things.

Virtual Routing and Forwarding (VRF). A technology that allows multiple instances of a Routing Information Base (RIB) to co-exist within the same router at the same time. Multiple VRFs inside a virtual router (VR) logically subdivide the RIBs. Service providers can use VRF technology to create a separate Virtual Private Network (VPN) for each of their customers. Therefore, the technology is also called VPN routing and forwarding.

virtual switch instance (VSI). A mechanism for VLANs to pass packets to other VLANs without sending the packets through a router. With a VSI, the switch recognizes packet destinations that are local to the sending VLAN and bridges (switches) those packets. Only packets destined for another VLAN are routed.

A VSI is similar to the bridging defined in IEEE 802.1Q; a frame is switched, based on the destination MAC and membership in a Layer 2 (L2) VPN. A VSI floods unknown, broadcast, or multicast frames to all ports associated with the VSI.

virtualization. A technology that abstracts the physical characteristics of a machine, creating a logical version of it, including creating logical versions of entities such as operating systems and network resources. See also hypervisor, virtual machine (VM).

vNIC (Virtual Network Interface Card). Software that behaves like a Ethernet hardware adapter. It has a MAC address, and it sends and receives Ethernet frames.

VPN routing and forwarding. See Virtual Routing and Forwarding (VRF).

vSwitch (Virtual Switch). Software that behaves like a physical Ethernet switch. A vSwitch connects virtual machine (VM) instances in a virtual network at layer 2:

- Connects vNIC (Virtual Network Interface Card) instances from multiple VMs to virtual ports
- Connects physical network interface cards to virtual ports
- Uplinks to the physical network

A vSwitch maintains a MAC address table and routes traffic to specific ports, rather than repeating traffic on all ports. A vSwitch can include other features found in physical Ethernet switches, such as VLANs.

See also Open vSwitch (OVS).

W

weighted fair queuing (WFQ). Queue scheduling discipline where each queue has a weight and is assigned a different percentage of output port bandwidth. WFQ supports variable-length packets so that flows with larger packets are not allocated more bandwidth than flows with smaller packets.

WFQ classifies traffic as high- or low-bandwidth with low-bandwidth traffic getting priority and high-bandwidth traffic sharing what is left over. If traffic bursts ahead of the rate at which the interface can transmit, new high-bandwidth traffic is discarded after a congestive-messages threshold has been reached.

WFQ provides preferential treatment for higher priority traffic while preventing total starvation of lower priority traffic under sustained overload conditions.

weighted random early detection (WRED). Congestion avoidance mechanism which prevents an output queue from ever filling to capacity. WRED provides separate thresholds and weights for different IP precedences, allowing you to provide different qualities of service in regard to packet dropping for different traffic types. Standard traffic may be dropped more frequently than premium traffic during periods of congestion.

weighted round-robin queuing (WRR). Queue scheduling discipline that supports flows with significantly different bandwidth requirements. Each queue can be assigned a weight that is relative to other queues. WRR ensures that lower-priority queues are not denied access to buffer space and output port bandwidth. At least one packet is removed from each queue during each service round.

white box switch. In computer hardware, a white box is a server without a well-known brand name made from commonly available parts. White box switches are like white box servers, offering low cost without the brand name or tight integration of silicon and network software features.

Traditional black box switches are built with vertically integrated hardware and software. Some vendors use custom application-specific integrated circuit (ASIC) components to boost performance and add features, which adds to the cost. A white box switch decouples the software from the switching hardware. By decoupling software and hardware, customers have more flexibility and can potentially change software without changing hardware.

A white box switch runs a network operating system on generic x86 hardware with “merchant silicon” chipsets from manufacturers such as Broadcom, Centec, Intel, Marvell, and Mellanox. White box switches rely on an operating system such as Linux to integrate the Layer 2 (L2)/Layer 3 (L3) networking functions.

White box switches do not have the same complex features as black box switches because most interact with Software-Defined Networking (SDN) controllers to make forwarding and control plane decisions from a centralized point for all switches in the network. The SDN controller uses OpenFlow (or another southbound API) to program the forwarding table of the white box switches.

Some vendors sell a complete white box solution with the operating system already installed, while others supply just the “bare-metal” switch and you buy the operating system direct from the software vendor.

wide area network (WAN). A network that provides communication services to a geographic area larger than that served by a Local Area Network (LAN) and that may use or provide public communication facilities.

wire speed. The ability of a device to achieve throughput equal to the maximum throughput of a communication standard.

Y

YANG. A data modeling language that specifies the syntax and semantics for NETCONF (Network Configuration Protocol) operations, notification events, and database content. YANG tools can automate behavior within the NETCONF protocol for clients and servers.

YANG can model both configuration and state data of network elements. YANG structures the data definitions into tree structures and provides many modeling features, including an extensible type system, formal separation of state and configuration data and a variety of syntactic and semantic constraints. YANG data definitions provide a strong set of features for extensibility and reuse. Defined in RFC 6020.

Z

ZebHA. An IP Infusion product that ensures a pre-agreed level of operational performance by minimizing system downtime. A ZebHA system operates redundant nodes that can provide continued service when a node fails. High availability does not mean that components will never fail, but it ensures that the system is available when the user needs it even if components fail. ZebHA provides:

- Simplex-Active or Active-Standby (1+1) control plane redundancy
- Reliable handling of operational, application, system and component failures;
- Strict Service Level Agreements (SLA) requirements of network operator customers

ZebHA supports protocol modules in Layer 2 (L2) and Layer 3 (L3).

There are two types of protocol recovery after a redundancy switchover: stateful switchover (SSO) and graceful restart.

ZebIC. An IP Infusion product that enables network equipment manufacturers to develop networking solutions based on leading silicon platforms. ZebIC allows manufacturers to deliver networking products built around this switching platform.

ZebIC enables developers to develop, integrate, and test a target platform while the actual hardware system is still under development. Pre-integrated with ZebOS-XP control plane platform, ZebIC:

- Separates hardware development from software development through the ZebOS abstraction layer.
- Isolates all of the hardware and operating system specific interactions into a small set of well-defined function calls for the control plane.

ZebM. An IP Infusion product that allows network equipment manufacturers to develop management functionality for their networking products. ZebM provides a software framework and APIs for building on-device management systems for network equipment. The ZebM framework contains these core components:

- CML (Central Management Layer), transaction-oriented middleware that connects configuration and operational data on all management interfaces within a network device. CML is used by any northbound management application to manage ZebOS-XP or any third-party control plane.
- SMI (Simple Management Interface), a series of southbound Interface modules to connect with OcNOS or any third party control plane protocol modules. SMI is the interface between the managed object and the CML.
- Model-driven northbound interface for automatic rendering of interfaces such as command-line interface (CLI) and NETCONF (Network Configuration Protocol).

ZebOS-XP. An IP Infusion product with Layer 2 (L2) and Layer 3 (L3) control plane software that allows network equipment manufacturers to rapidly add networking capabilities to communications products. ZebOS-XP is targeted at manufacturers who provide solutions in carrier transport, access, Carrier Ethernet, mobile backhaul, data center, and cloud networking, including solutions for enterprise private clouds, hybrid clouds, and public clouds

The ZebOS-XP networking protocol modules conform to leading Institute of Electrical and Electronics Engineers (IEEE), Internet Engineering Task Force (IETF), Metro Ethernet Forum (MEF), and other industry standards.
